

# Internet Protocol Security

CS155 Computer and Network Security

Stanford University

# The Internet

Global network that provides **best-effort** delivery of **packets** between connected hosts

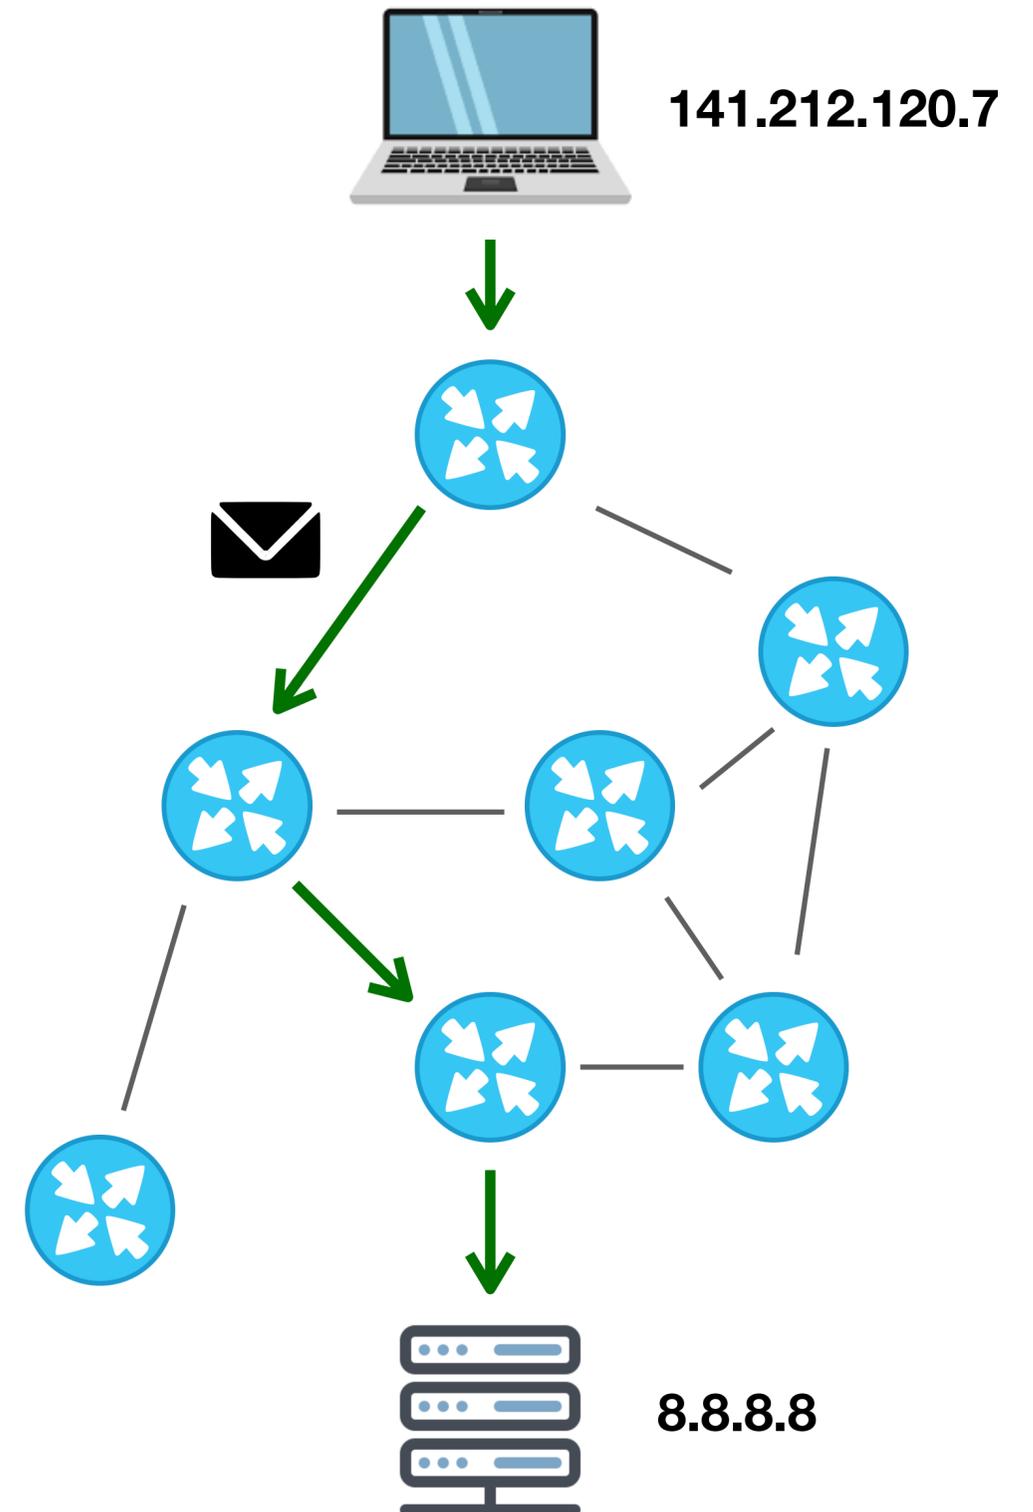

**Packet:** a structured sequence of bytes

**Header:** metadata used by network

**Payload:** user data to be transported

Every host has a unique identifier — IP address

Series of routers receive packets, look at destination address on the header and send it one hop towards the destination IP address

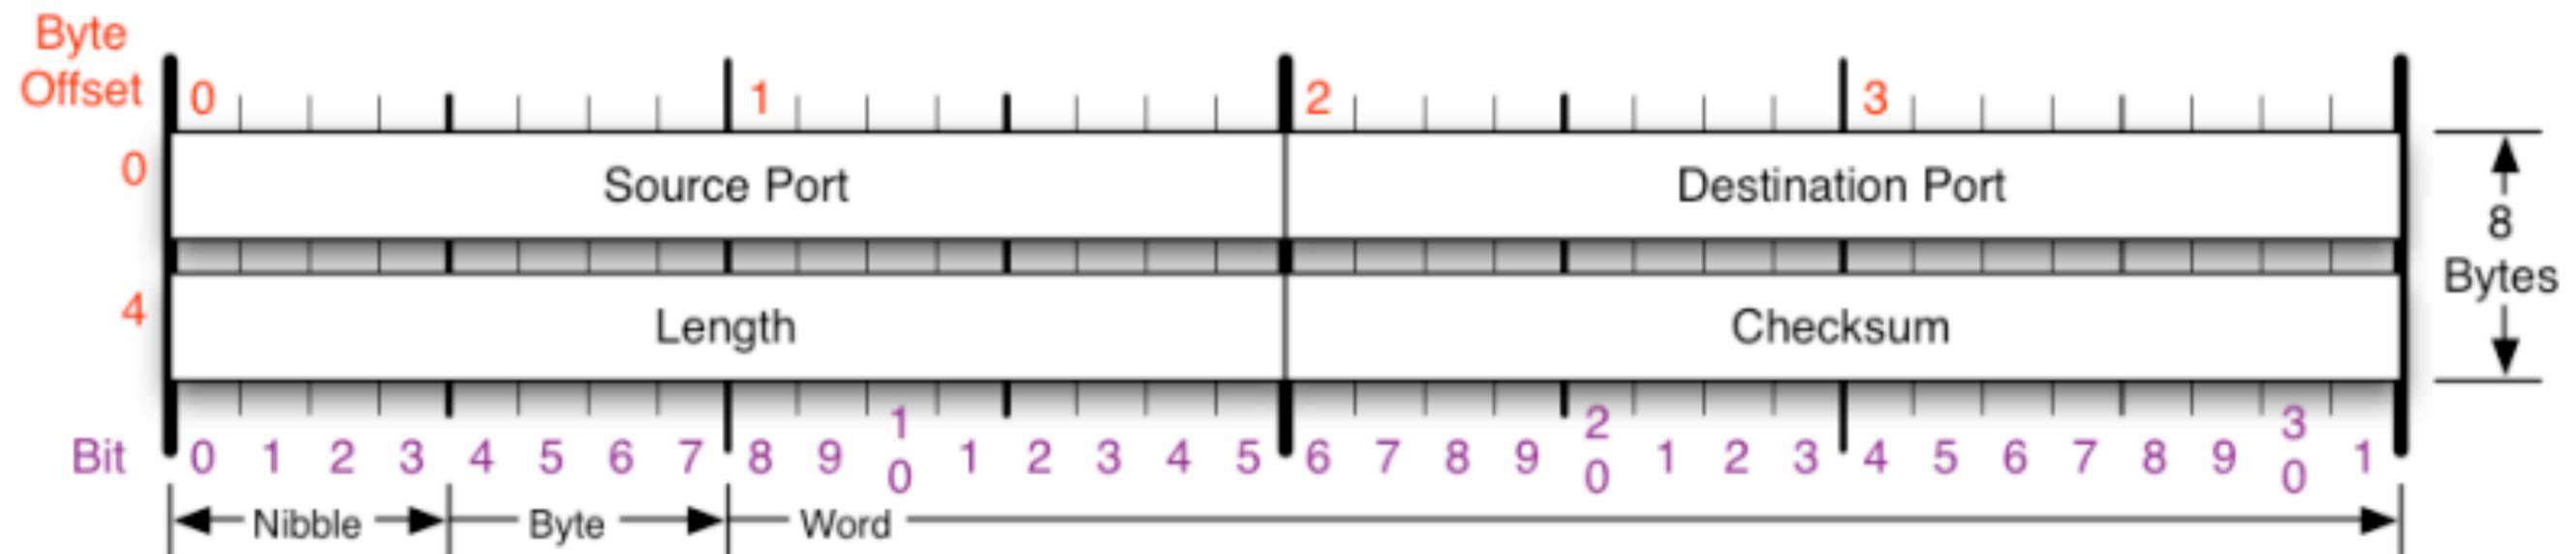

# Network Protocols

We define how hosts communicate in published network protocols

**Syntax:** How communication is structured (e.g., format and order of messages)

**Semantics:** What communication means. Actions taken on transmit or receipt of message, or when a timer expires. What assumptions can be made.

**Example: What bytes contain each field in a packet header**

# Protocol Layering

Networks use a stack of protocol layers

- Each layer has different responsibilities.
- Layers define abstraction boundaries

Lower layers provide services to layers above

- Don't care what higher layers do

Higher layers use services of layers below

- Don't worry about how it works

**Application**

**Transport**

**Network**

**Data Link**

**Physical**

# OSI 5 Layer Model

**Physical**

How do bits get translated into electrical, optical, or radio signals

# OSI 5 Layer Model

## Data Link

How to get packet to the next hop. Transmission of data frames between two nodes connected by a physical link.

## Physical

How do bits get translated into electrical, optical, or radio signals

# OSI 5 Layer Model

## Network

Responsible for packet forwarding. How to get a packet to the final destination when there are many hops along the way.

## Data Link

How to get packet to the next hop. Transmission of data frames between two nodes connected by a physical link.

## Physical

How do bits get translated into electrical, optical, or radio signals

# OSI 5 Layer Model

## Transport

Allows a client to establish a connection to specific services (e.g., web server on port 80). Provides reliable communication.

## Network

Responsible for packet forwarding. How to get a packet to the final destination when there are many hops along the way.

## Data Link

How to get packet to the next hop. Transmission of data frames between two nodes connected by a physical link.

## Physical

How do bits get translated into electrical, optical, or radio signals

# OSI 5 Layer Model

## Application

Defines how individual applications communicate. For example, **HTTP** defines how browsers send requests to web servers.

## Transport

Allows a client to establish a connection to specific services (e.g., web server on port 80). Provides reliable communication.

## Network

Responsible for packet forwarding. How to get a packet to the final destination when there are many hops along the way.

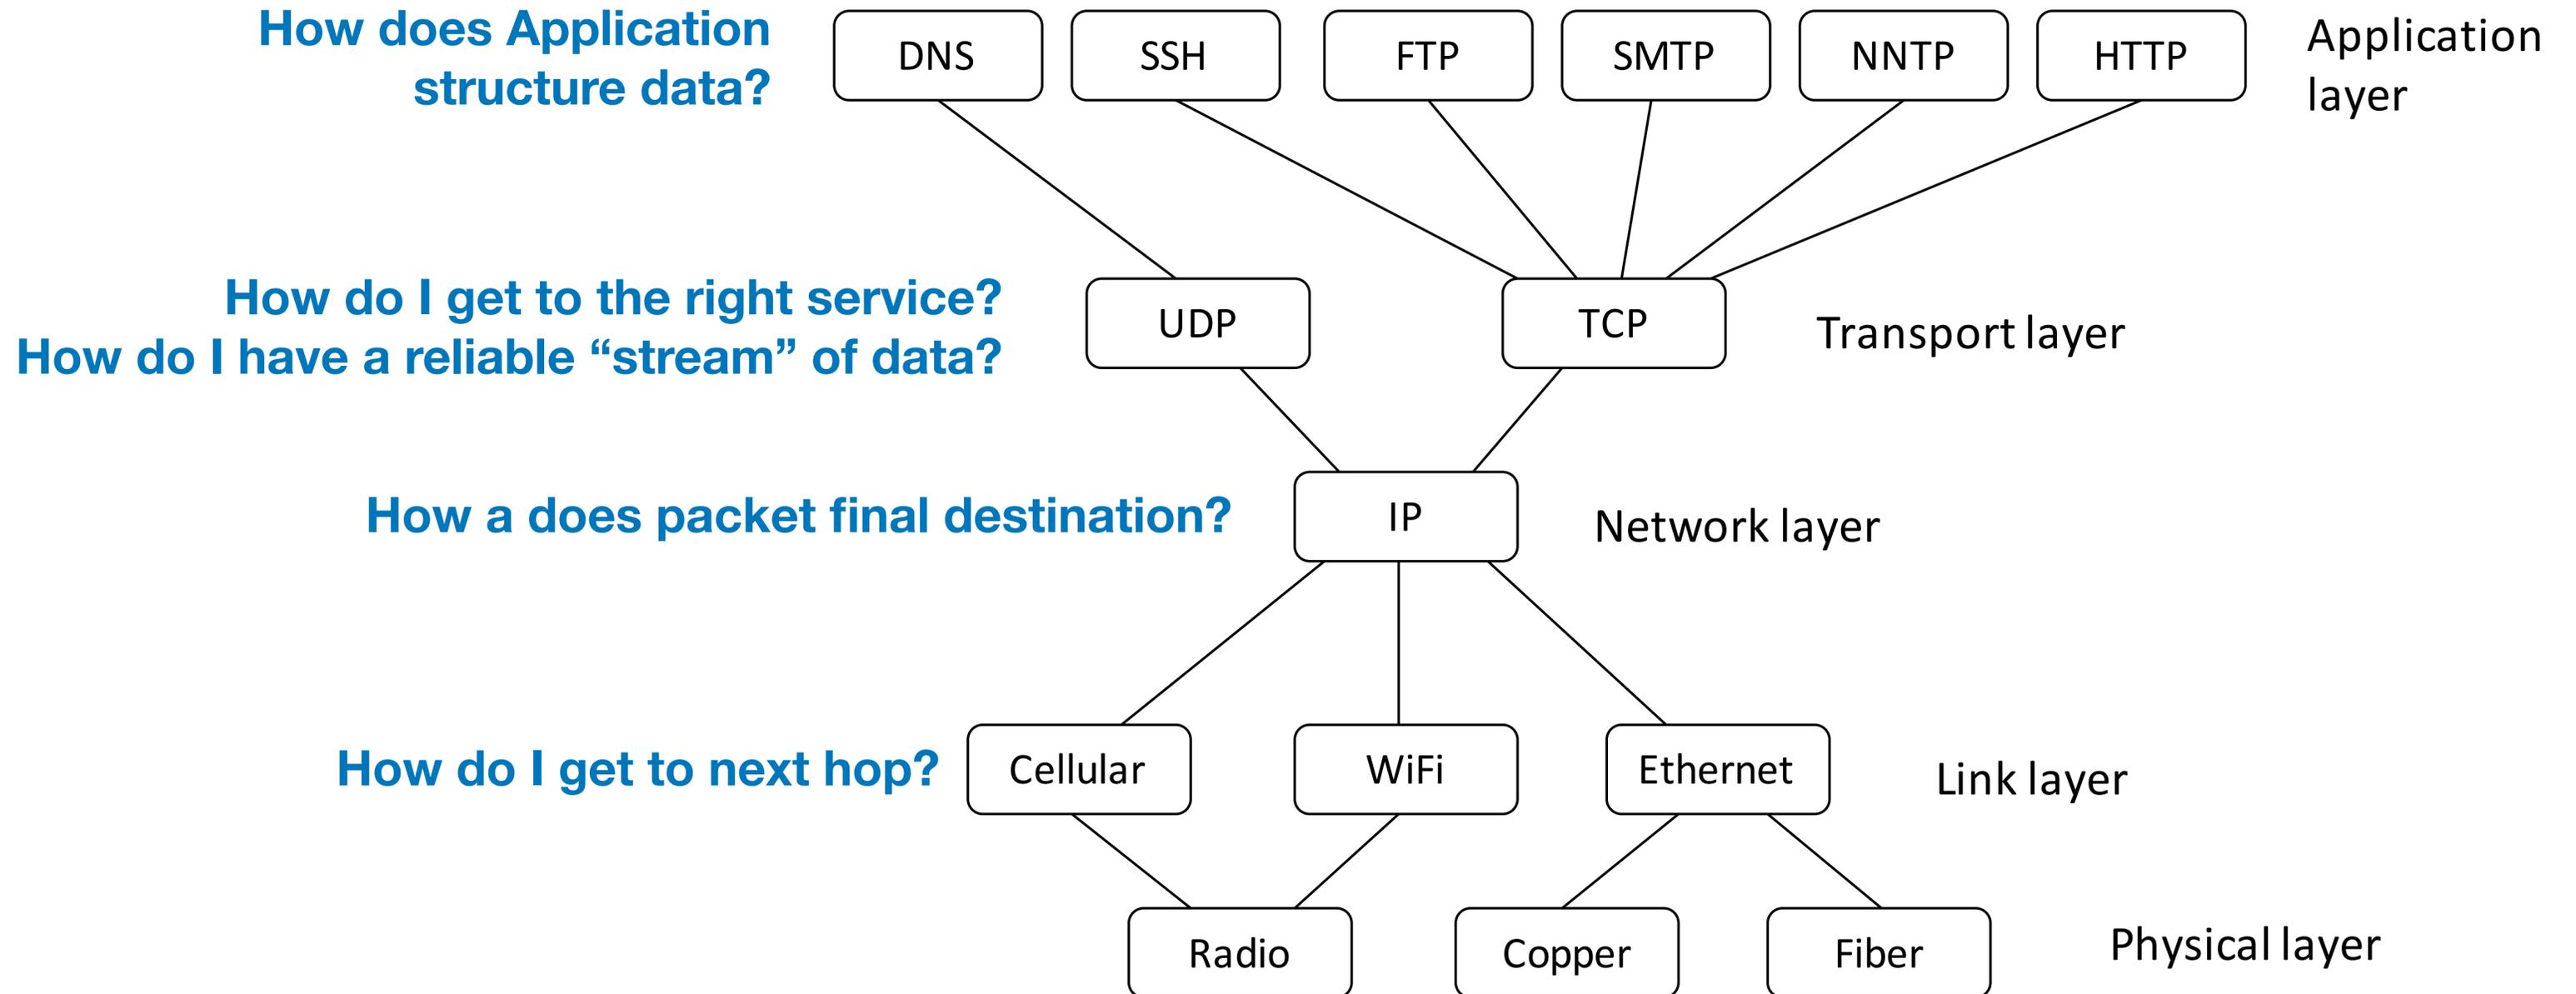

## Data Link

How to get packet to the next hop. Transmission of data frames between two nodes connected by a physical link.

## Physical

How do bits get translated into electrical, optical, or radio signals

# IP — The Narrow Waist

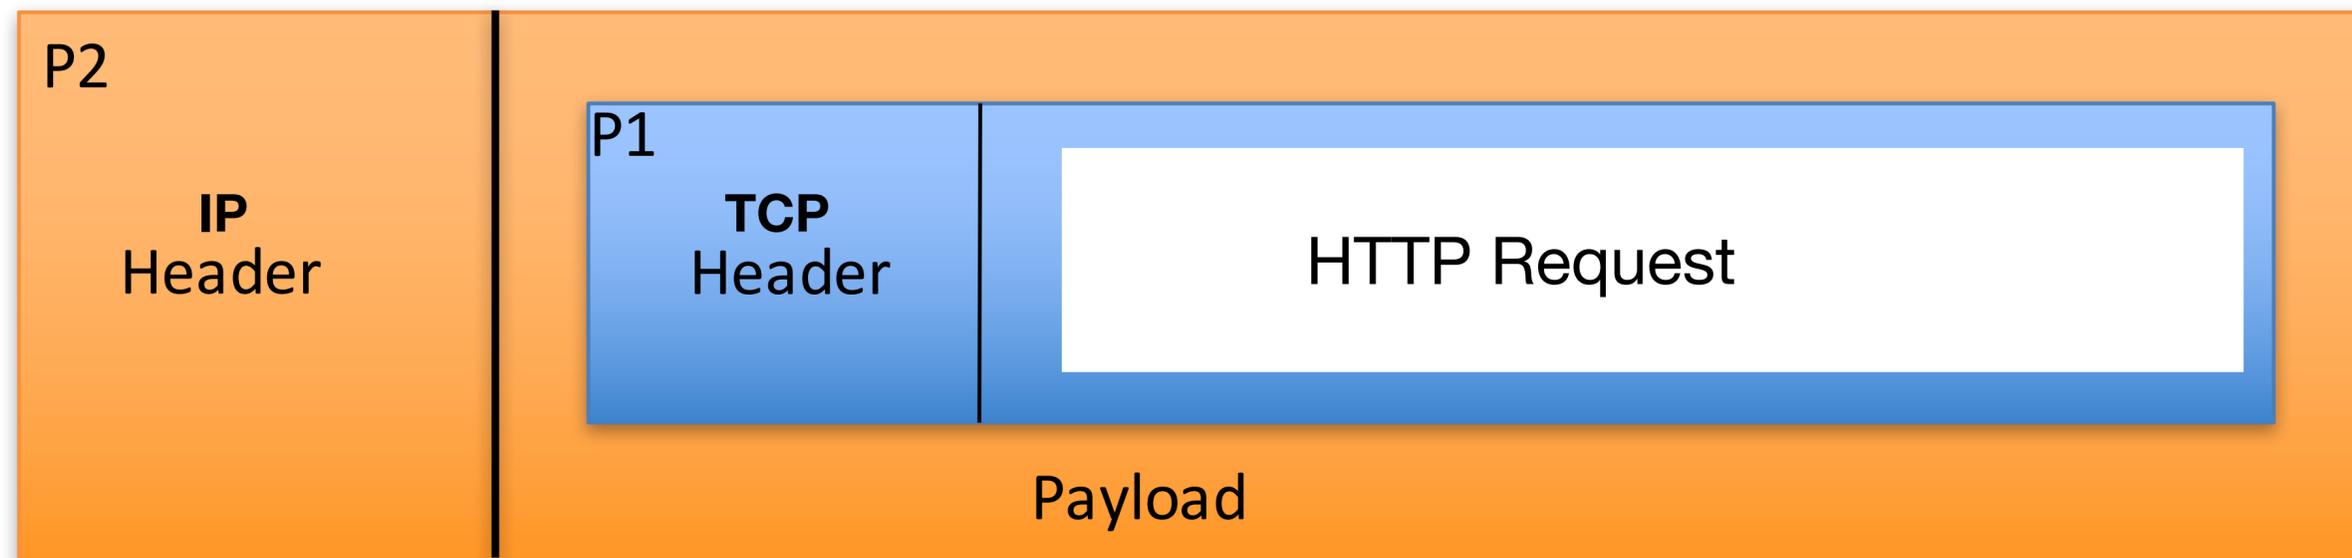

# Packet Encapsulation

Protocol N1 can use the services of lower layer protocol N2

A packet P1 of N1 is encapsulated into a packet P2 of N2

The payload of p2 is p1

The control information of p2 is derived from that of p1

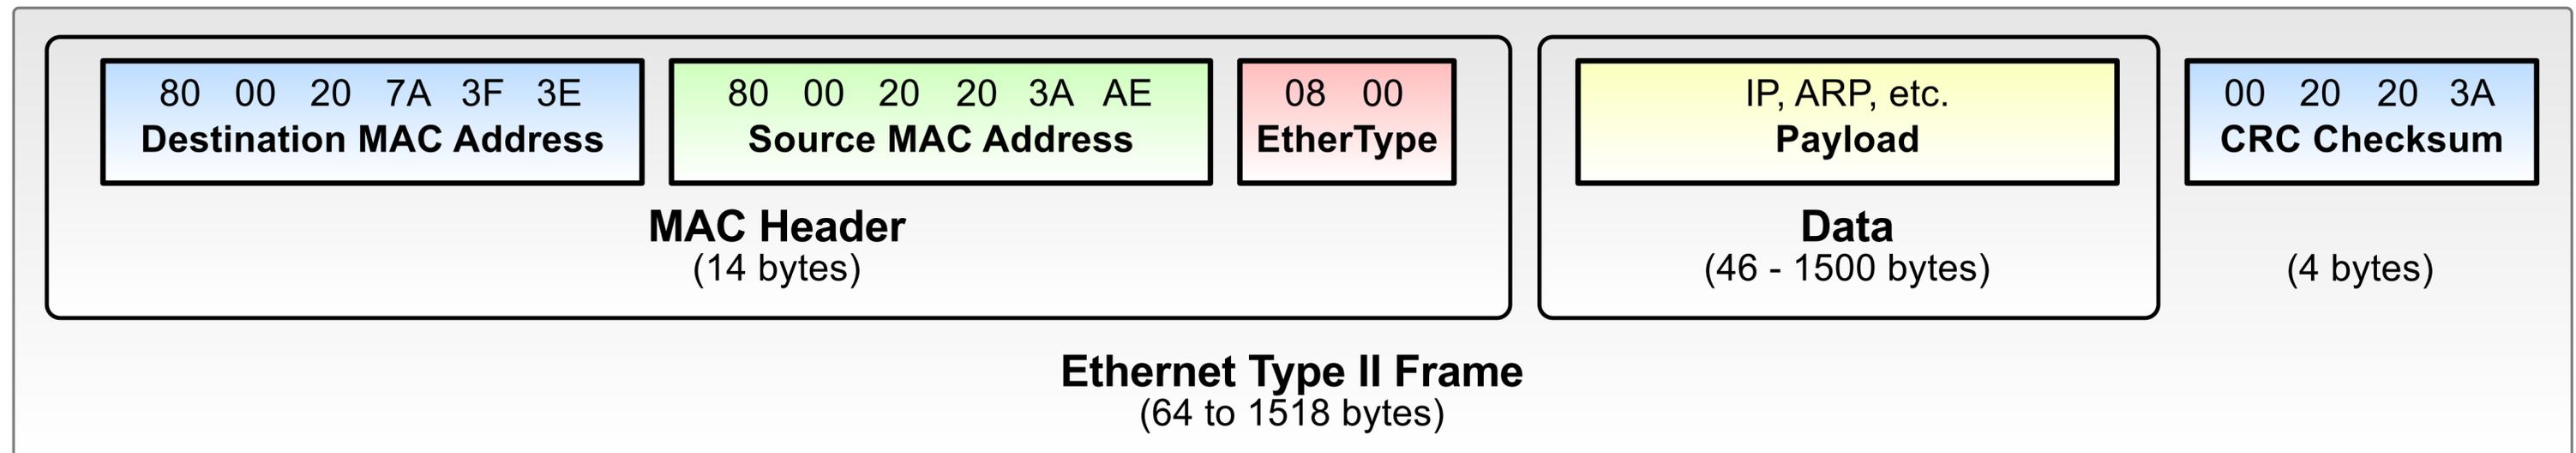

# Link Layer

**Assumes:** Local nodes are physically connected

**Task:** Transfer bytes between two hosts on the physically connected network

# Ethernet

Most common Link Layer Protocol. Let's you send packets to other local hosts.

At layer 2 (link layer) packets are called *frames*

MAC addresses: 6 bytes, universally unique

EtherType gives layer 3 protocol in payload

0x0800: IPv4

0x0806: ARP

0x86DD: IPv6

# Ethernet

```
[zakhir@scratch-01:~]$ ifconfig
ens160: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
  inet 10.216.2.64 netmask 255.255.192.0 broadcast 10.216.63.255
  inet6 fe80::250:56ff:fe86:b203 prefixlen 64 scopeid 0x20<link>
  ether 00:50:56:86:b2:03 txqueuelen 1000 (Ethernet)
  RX packets 1404151714 bytes 1784388363701 (1.7 TB)
  RX errors 0 dropped 73 overruns 0 frame 0
  TX packets 1155689210 bytes 6010503085464 (6.0 TB)
  TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0
```

# Internet Protocol (IP)

**Internet Protocol (IP)** defines what packets that cross the Internet need to look like to be processed by routers

Every host is assigned a unique identifier (“IP Address”)

Every packet has an IP header that indicates its sender and receiver

Routers forward packet along to *try* to get it to the destination host

Rest of the packet should be ignored by the router

# IP Addresses

**IPv4:** 32-bit host addresses

Written as 4 bytes in form A.B.C.D

where A,...,D are 8 bit integers in decimal

(called *dotted quad*) e.g. 192.168.1.1

**IPv6:** 128 bit host addresses

Written as 16 bytes in form AA:BB::XX:YY:ZZ

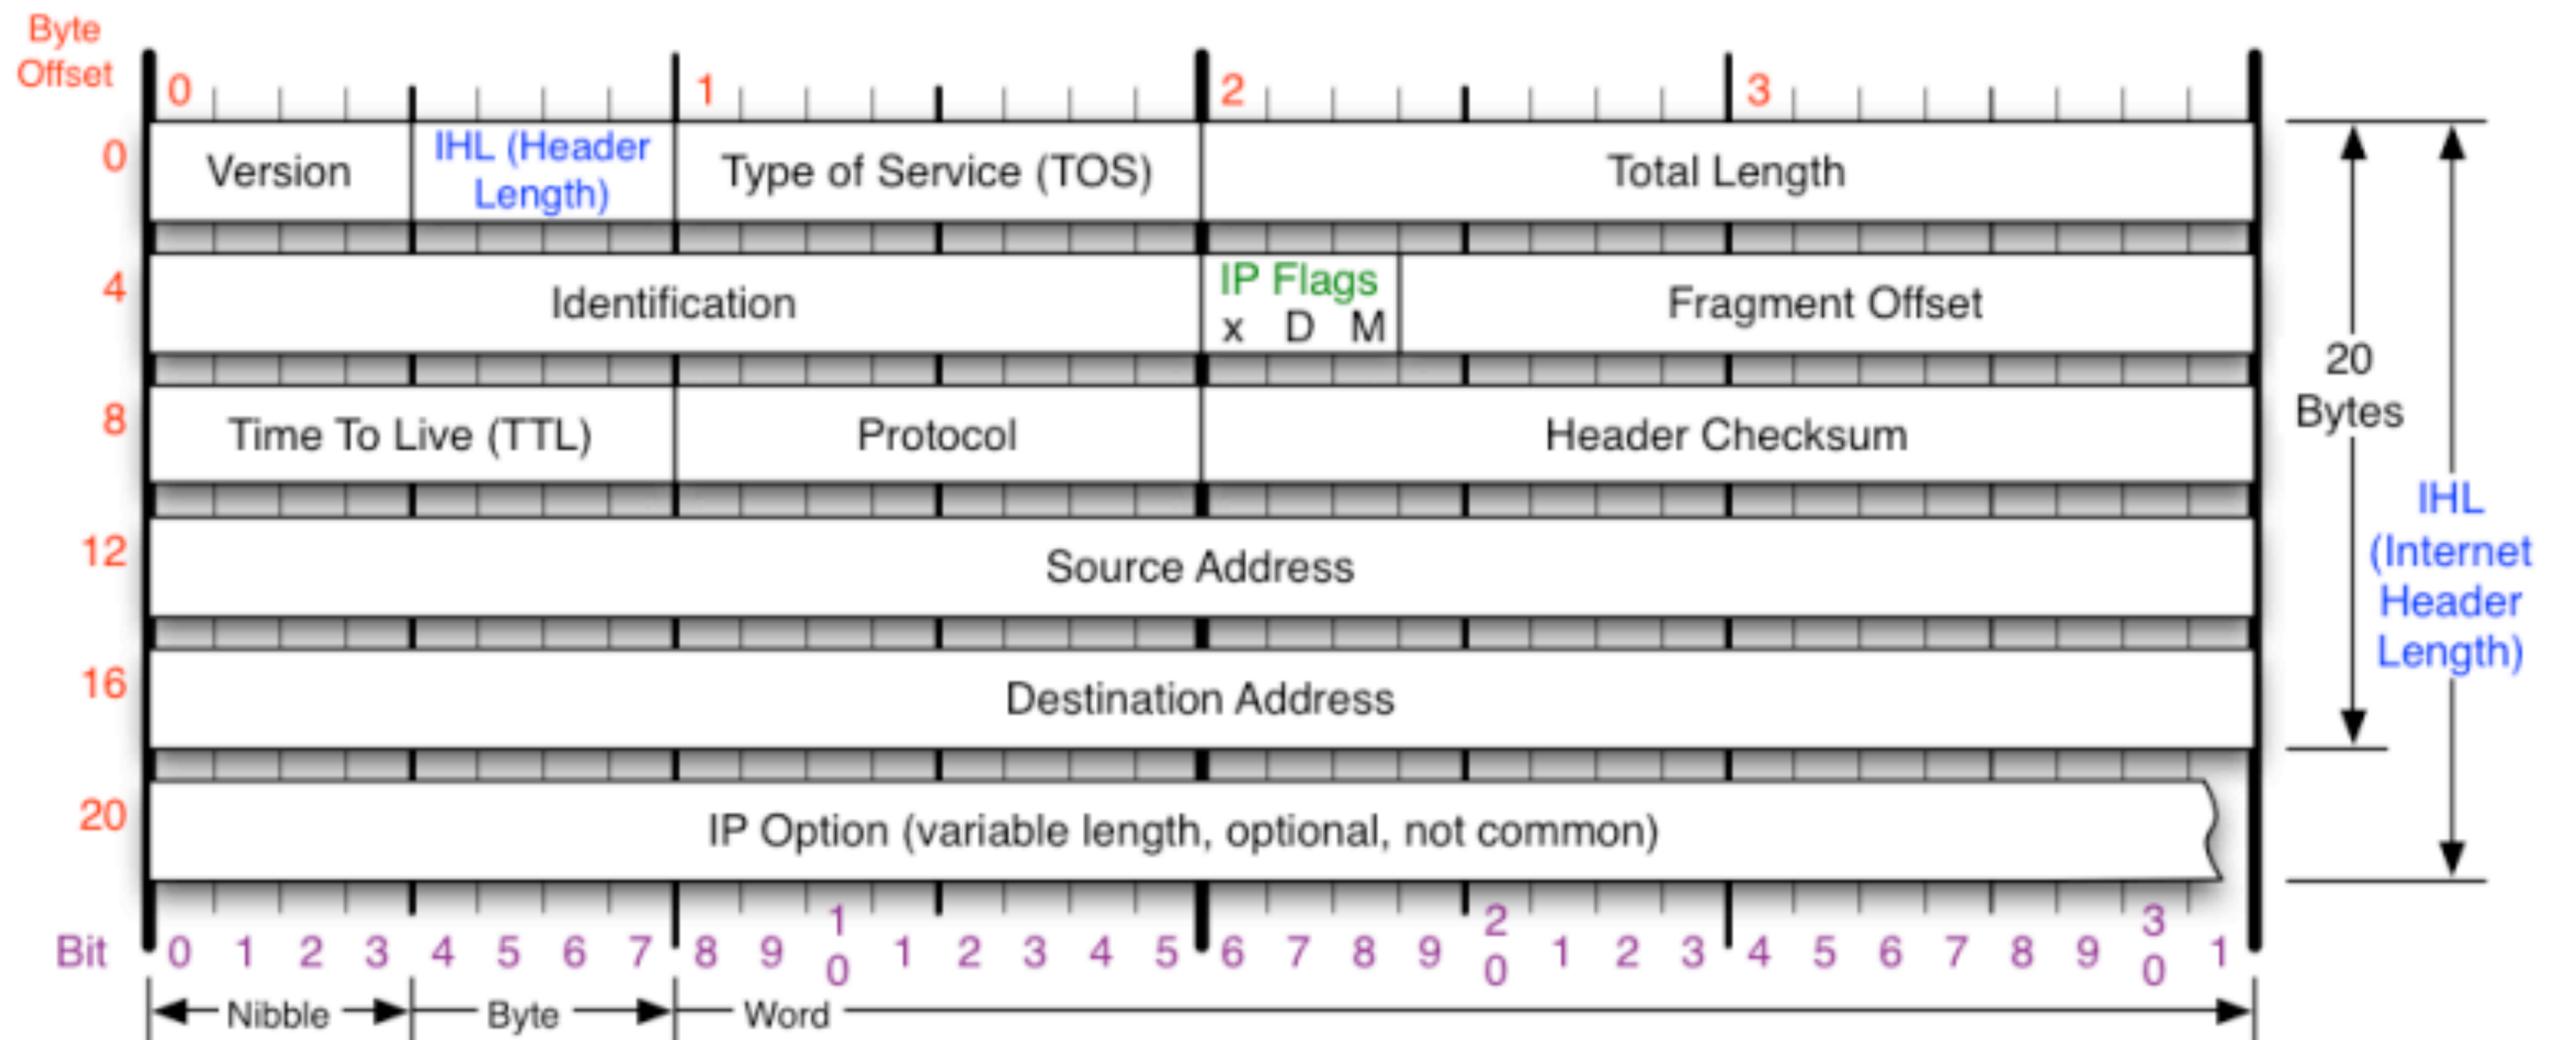

where AA,...,ZZ are 16 bit integers in hexadecimal

and :: implies zero bytes

e.g. 2620:0:e00:b::53 = 2620:0:e00:b:0:0:0:53

# IPv4 Header

Instruct routers and hosts what to do with a packet  
All values are filled in by the sending host

# Internet Protocol (IP)

## **Yes:**

Routing. If host knows IP of destination host, route packet to it.

Fragmentation and reassembly: Split data into packets and reassemble

Error Reporting: (maybe, if you're lucky) tell source it dropped your packet

## **No:**

Everything else. No ordering. No retransmission. No (real) error checking. No acknowledgement of receipt. No "connections". No security. Just packets.

# Two Problems

**Local:** How does a host know what MAC address their destination has given an IP address?

**Internet:** How does each router know where to send each packet next?

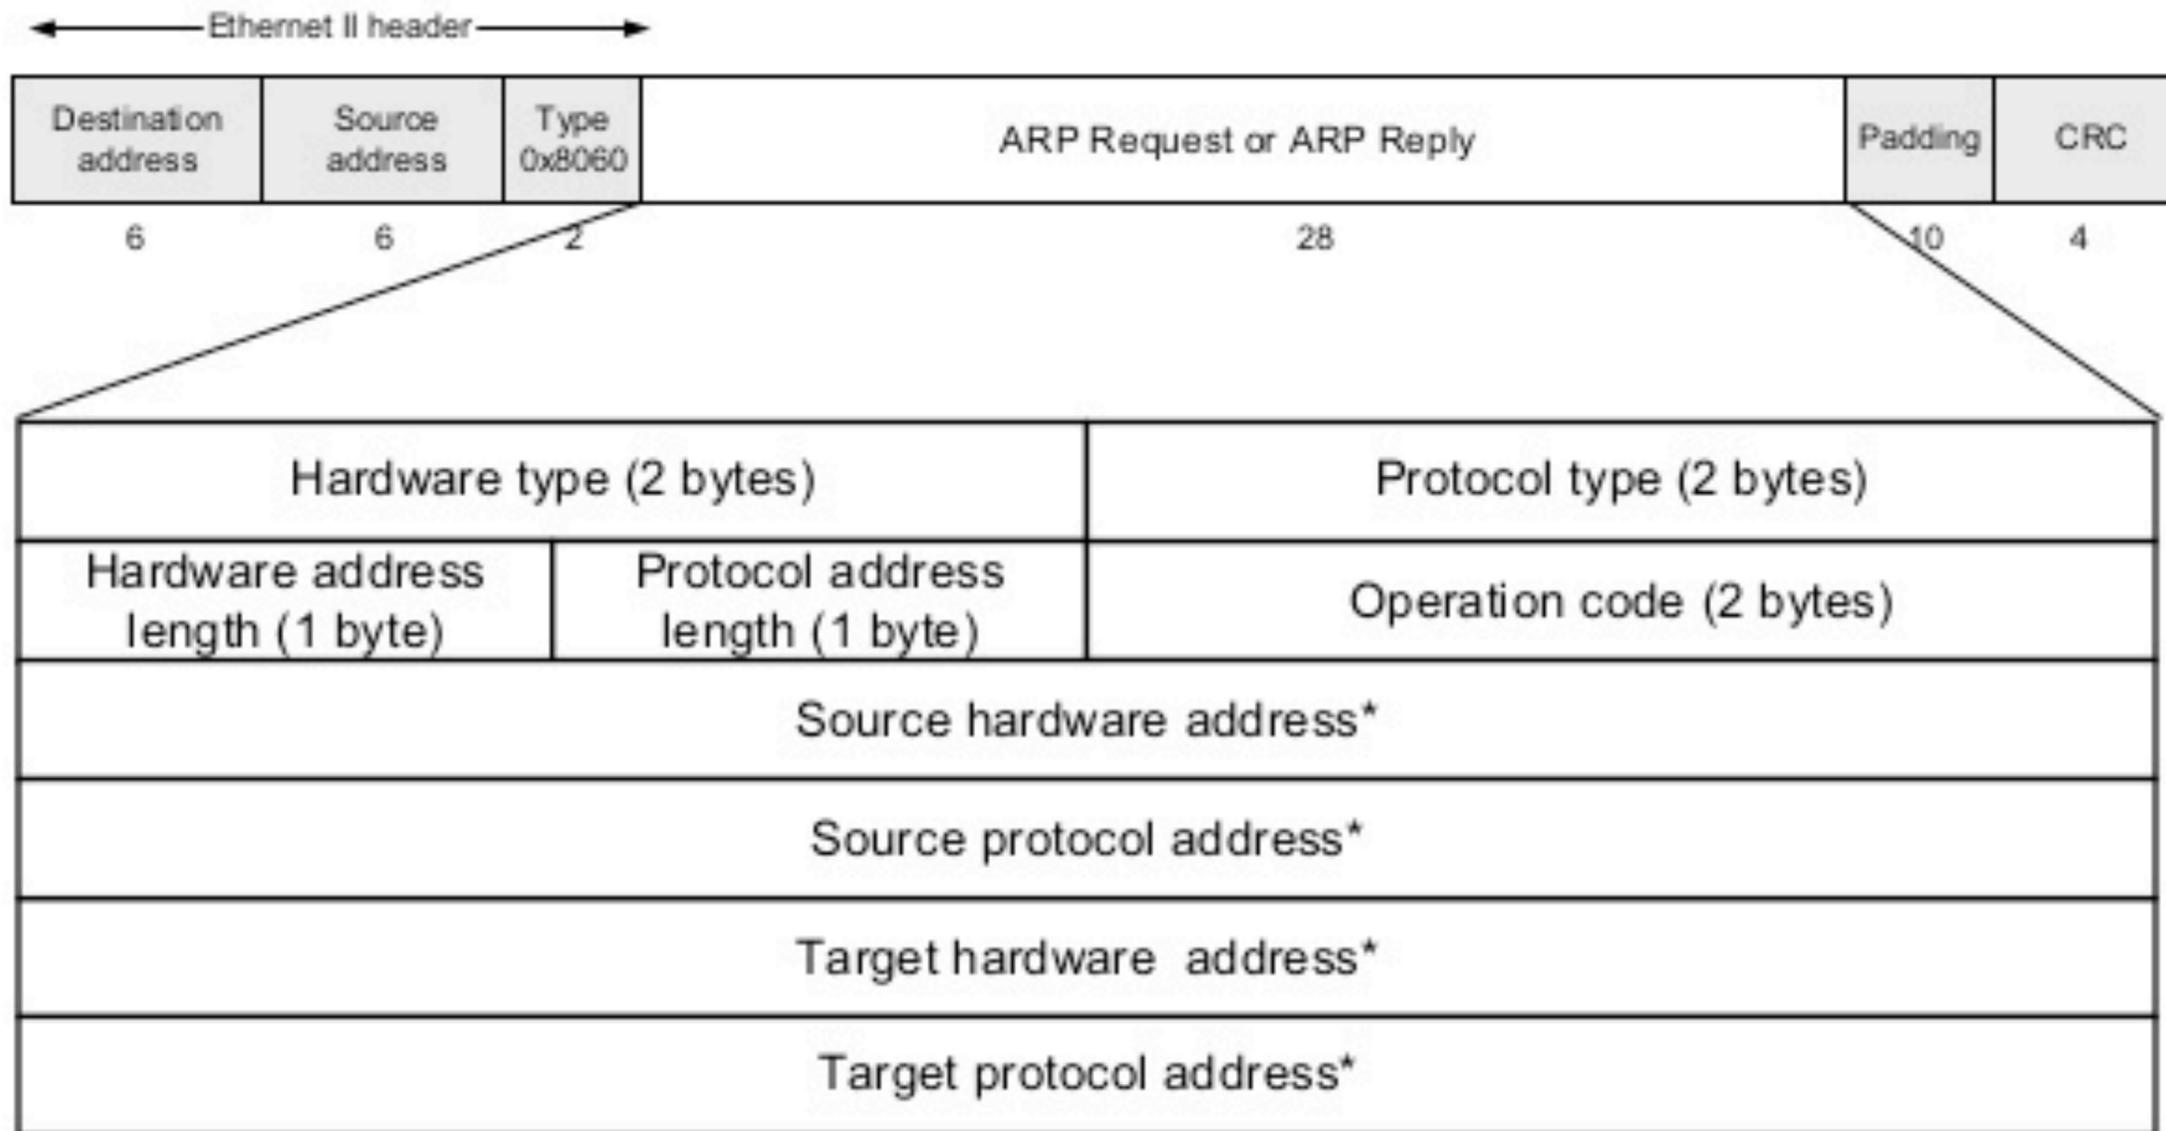

# ARP: Address Resolution Protocol

ARP is a Network protocol that lets hosts map IP addresses to MAC addresses

Host who needs MAC address  $M$  corresponding to IP address  $N$  broadcasts an ARP packet to LAN asking, “who has IP address  $N$ ?”

Host that has IP address  $N$  will reply, “IP  $N$  is at MAC address  $M$ .”

# ARP Packet

\* Note: The length of the address fields is determined by the corresponding address length fields

# ARP Security

Any host on the LAN can send ARP requests and replies: *any host can claim to be another host on the local network!*

This is called *ARP spoofing*

This allows any host X to force IP traffic between any two other hosts A and B to flow through X (*MitM!*)

Claim  $N_A$  is at attacker's MAC address  $M_X$

Claim  $N_B$  is at attacker's MAC address  $M_X$

Re-send traffic addressed to  $N_A$  to  $M_A$ , and vice versa

# Routing (BGP)

BGP (Border Gateway Protocol): protocol that allows routers to exchange information about their routing tables

Each router announces what it can route to all of its neighbors.

Every router maintains a global table of routes

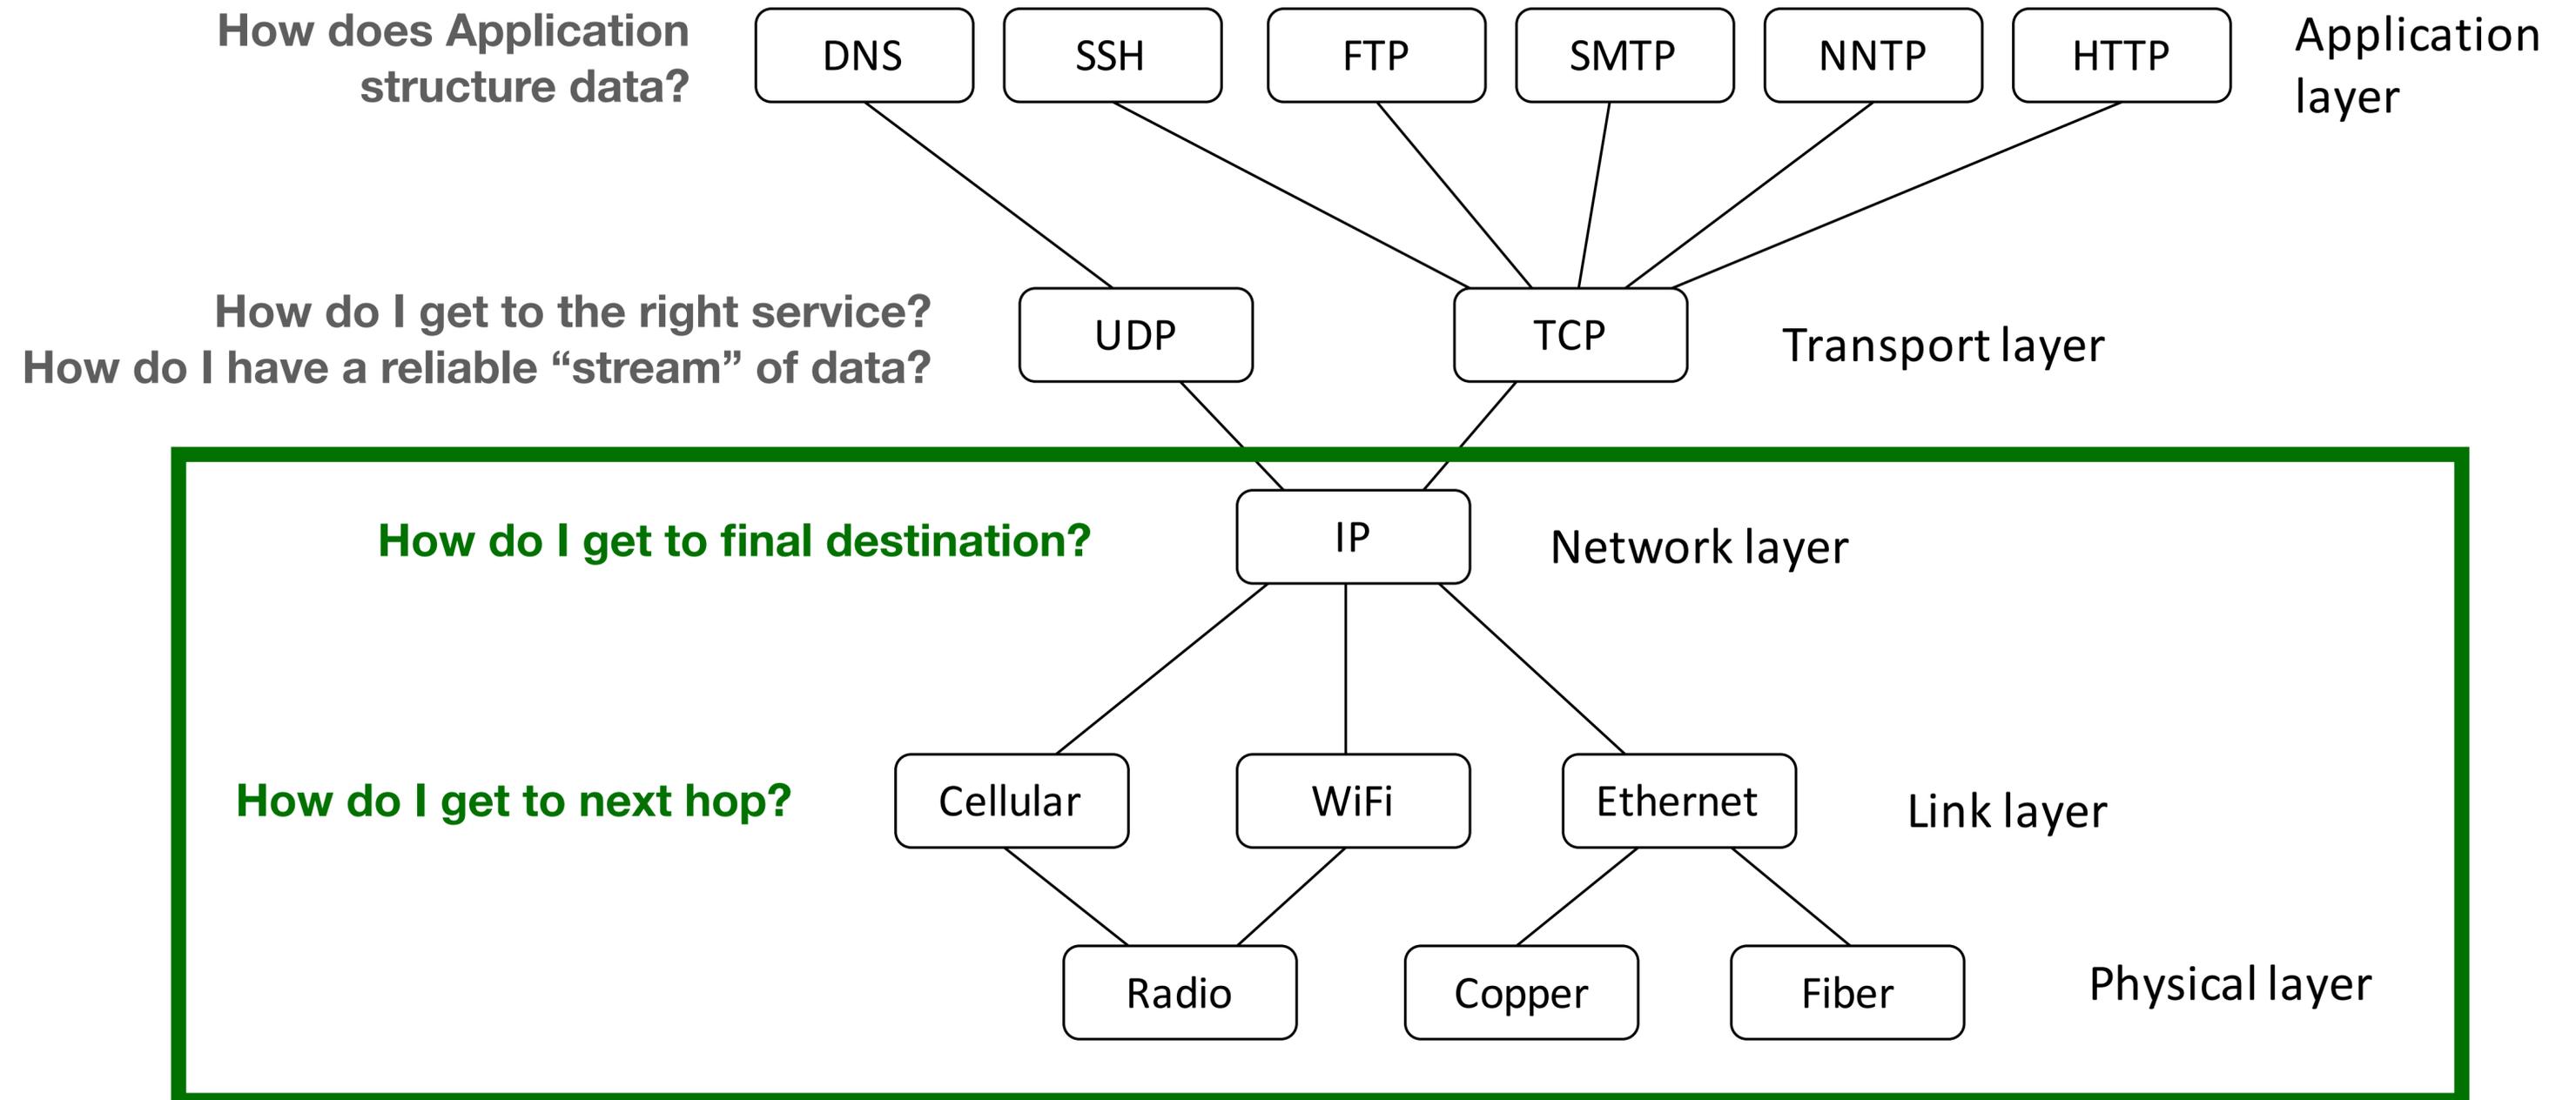

# Pakistan hijacks YouTube

On 24 February 2008, Pakistan Telecom (AS 17557) began advertising a small part of YouTube's (AS 36561) assigned network

PCCW (3491) did not validate Pakistan Telecom's (17557) advertisement for 208.65.153.0/24

Youtube offline.

# Protocol Layering

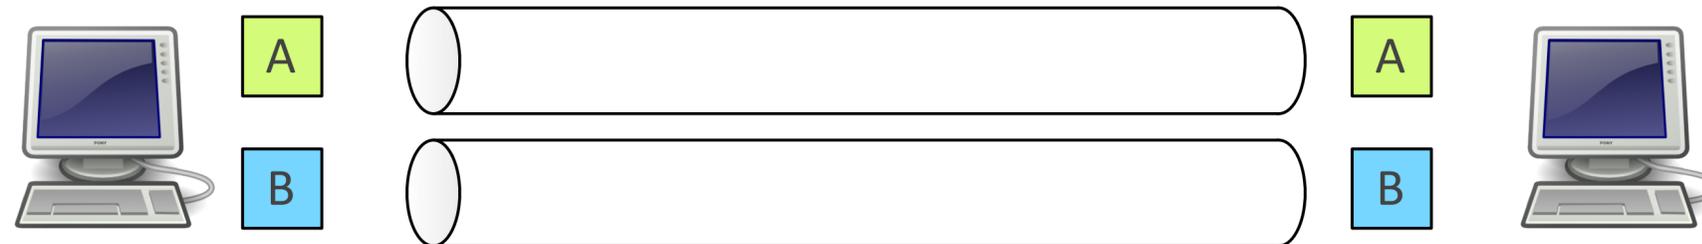

# Ports

Each application on a host is identified by a *port number*

TCP connection established between port *A* on host *X* to port *B* on host *Y*  
Ports are 1–65535 (16 bits)

Some destination port numbers used for specific applications by convention

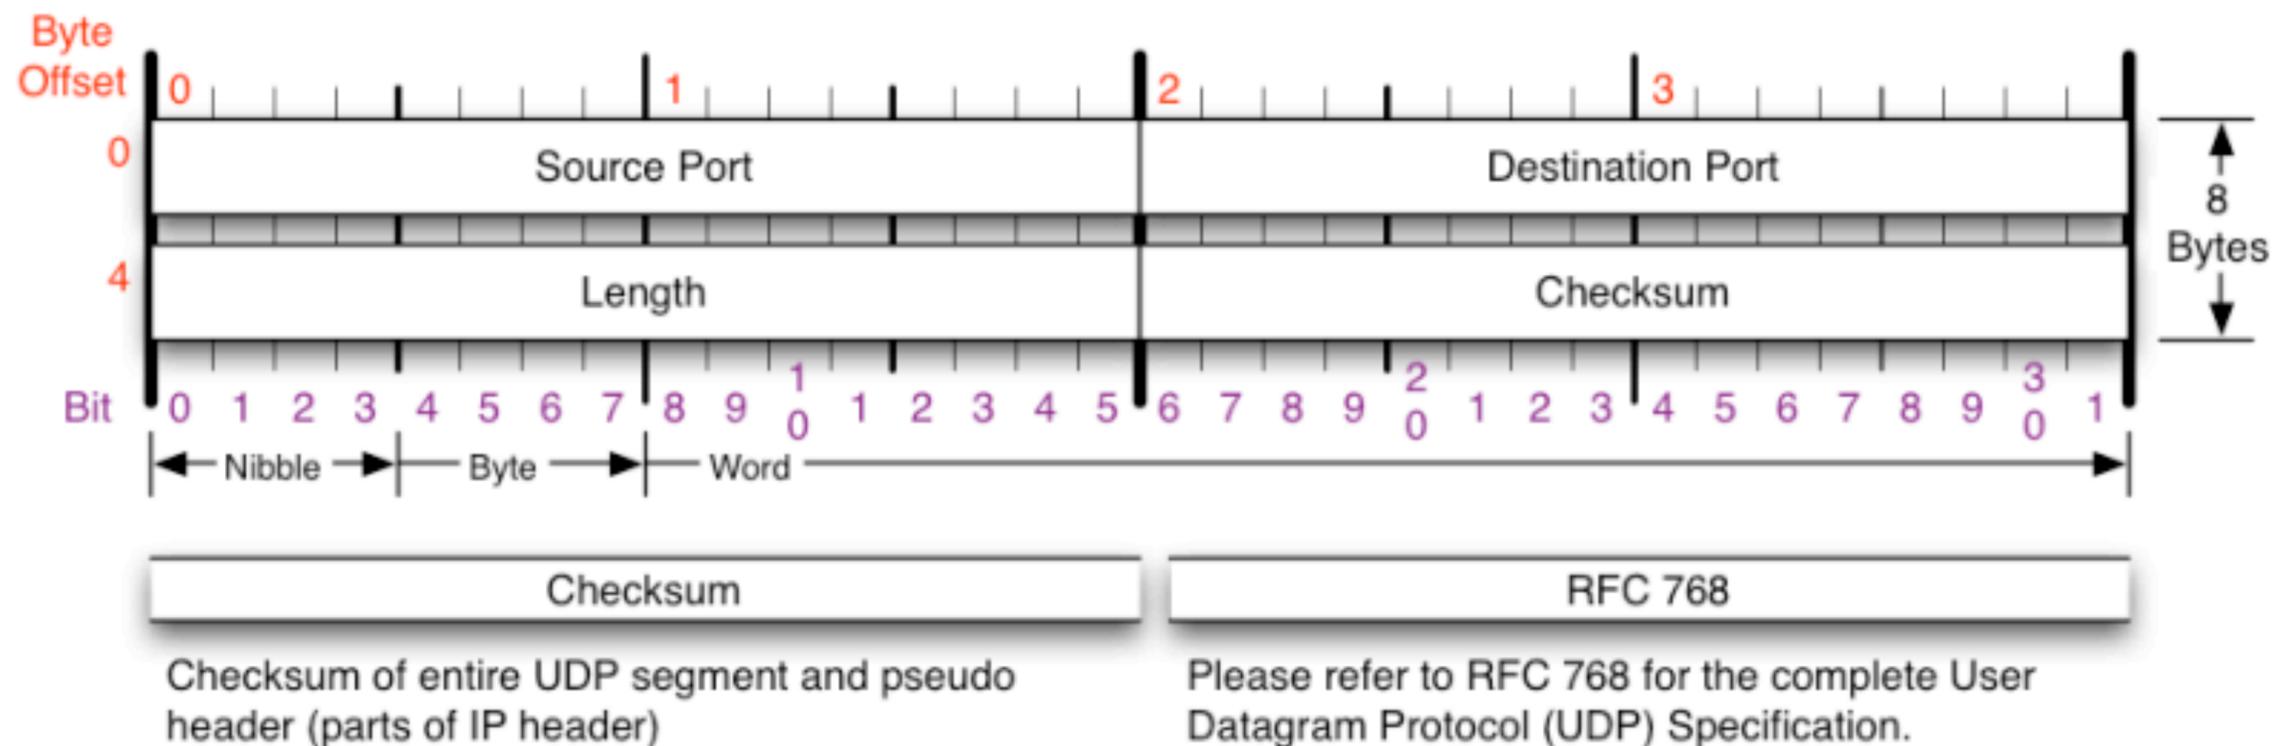

# Common Ports

Port	Application
80	HTTP (Web)
443	HTTPS (Web)
25	SMTP (mail)
67	DHCP (host config)
22	SSH (secure shell)
23	Telnet

# UDP (User Datagram Protocol)

**User Datagram Protocol (UDP)** is a transport layer protocol that is essentially a wrapper around IP

Adds ports to demultiplex traffic by application

# From Packets to Streams

Most applications want a stream of bytes delivered reliably and in-order between applications on different hosts

**Transmission Control Protocol (TCP)** provides...

- Connection-oriented protocol with explicit setup/teardown
- Reliable in-order byte stream
- Congestion control

Despite IP packets being dropped, re-ordered, and duplicated

# TCP Sequence Numbers

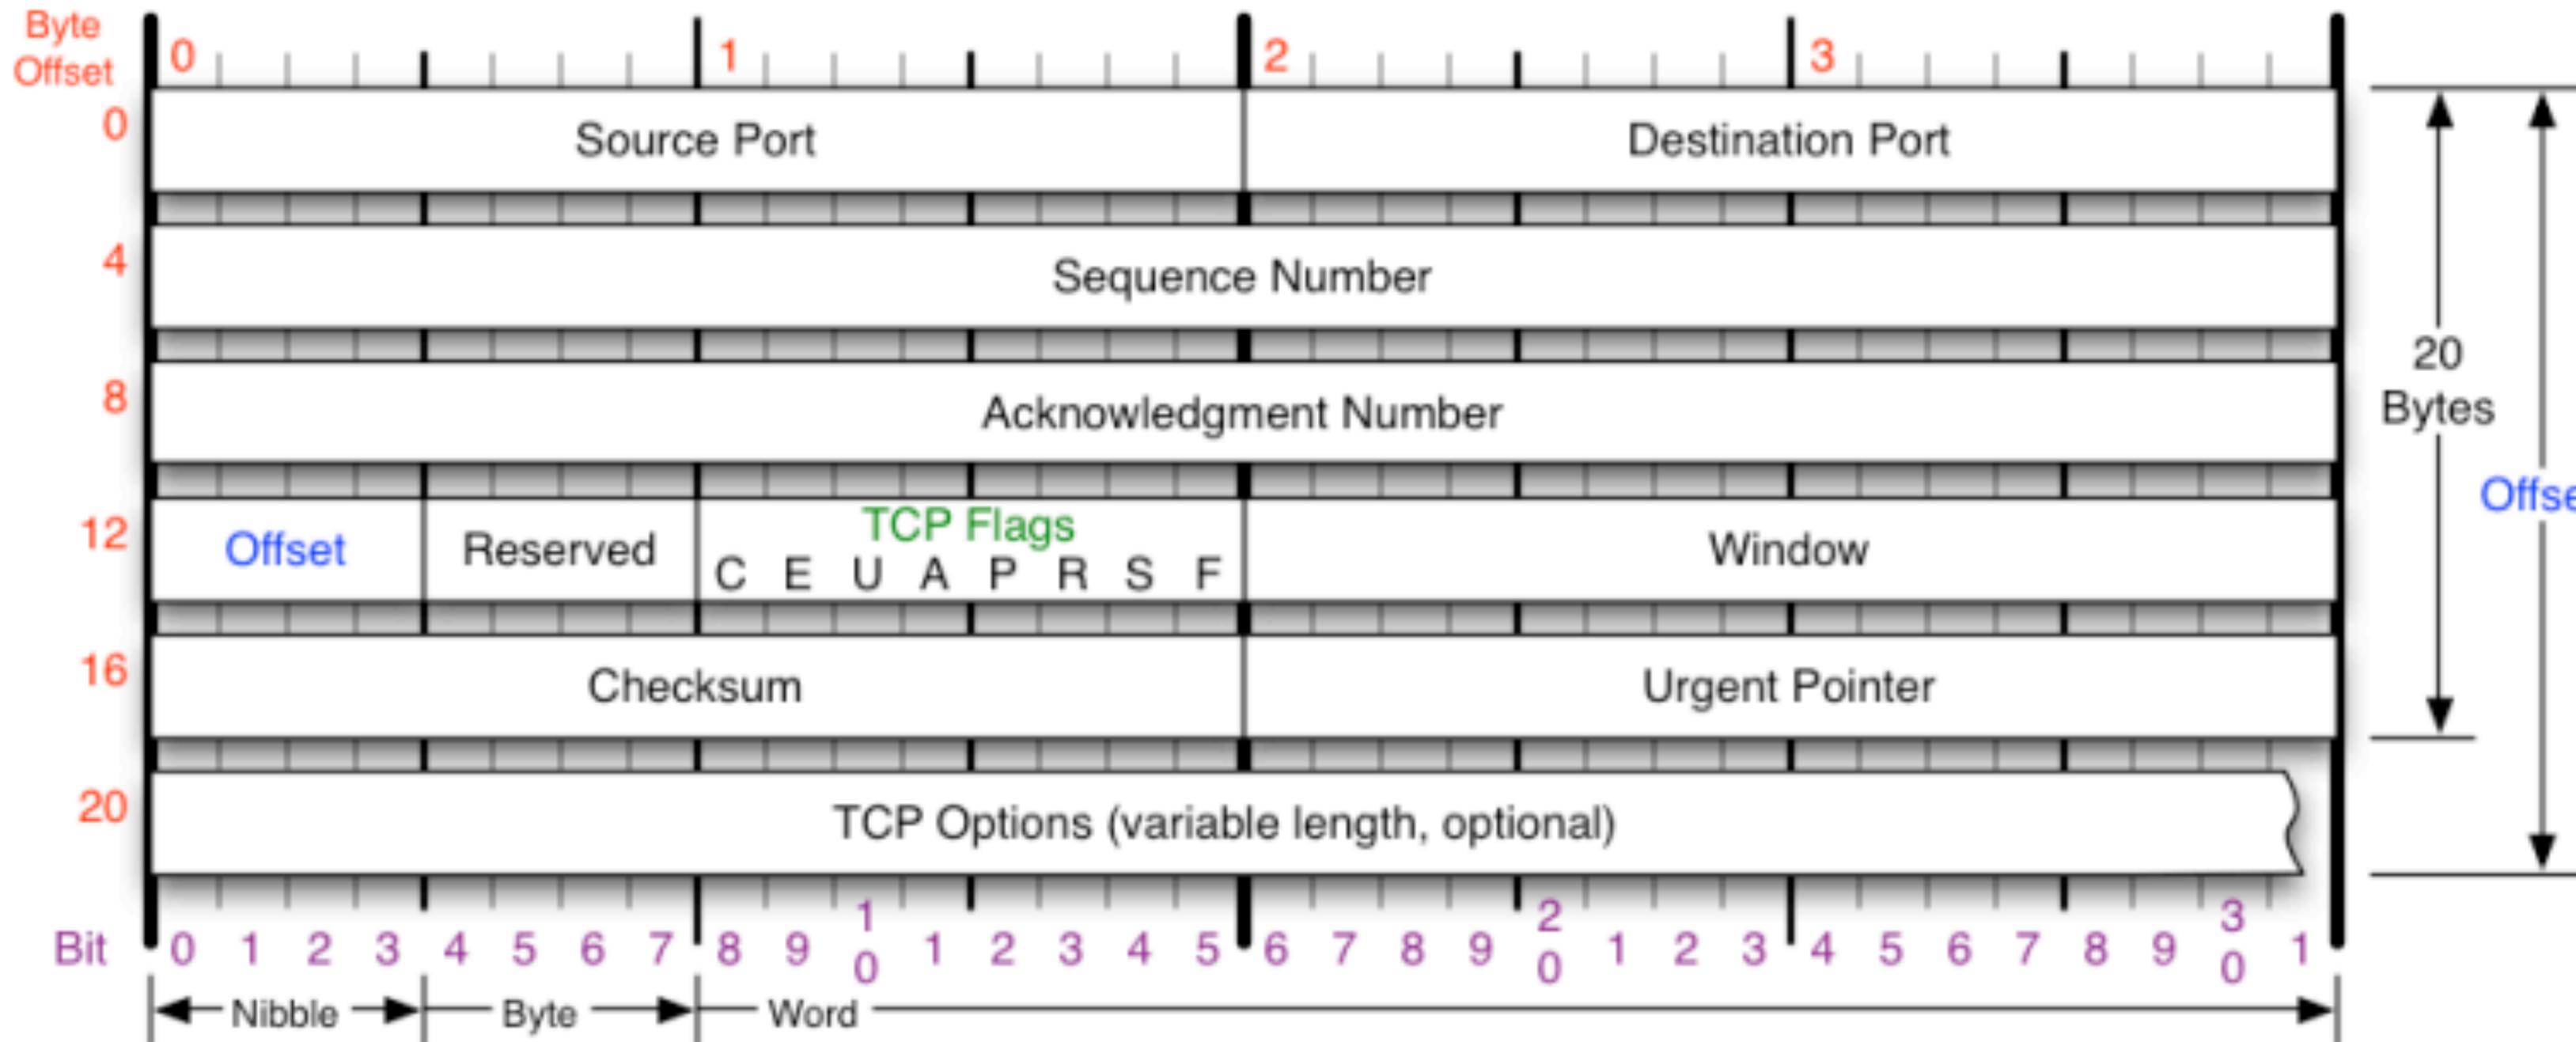

Two data streams in a TCP session, one in each direction

Bytes in data stream numbered with a 32-bit *sequence number*

Every packet has sequence number that indicates where data belongs

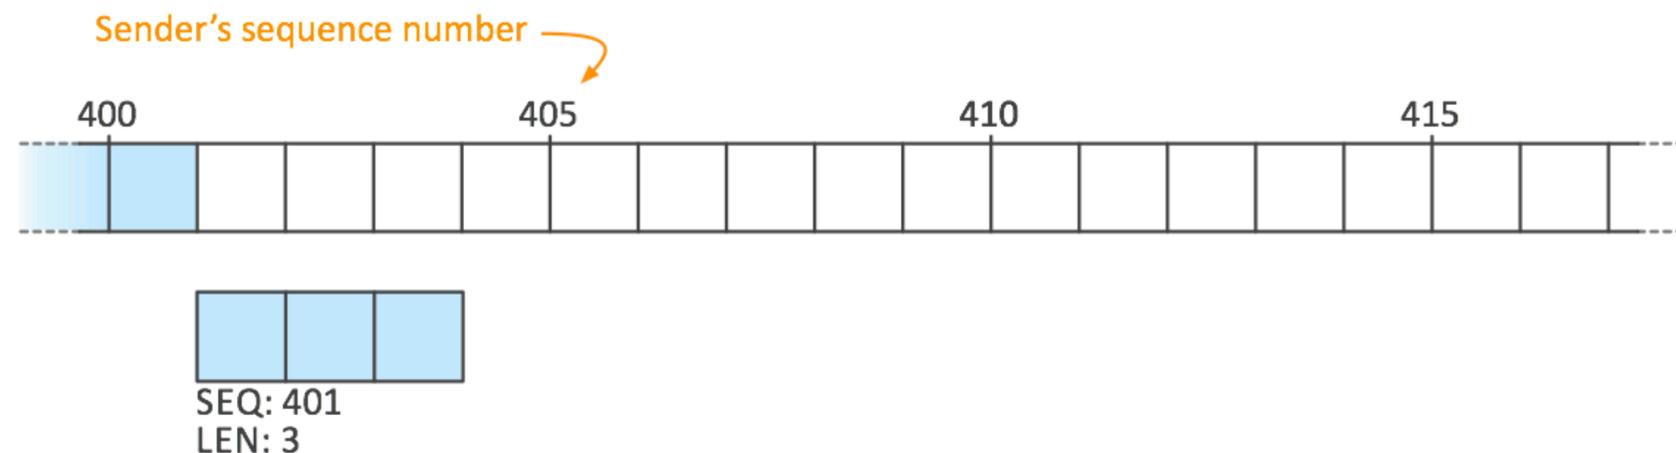

Receiver sends acknowledgement number that indicates data received

# TCP Packet

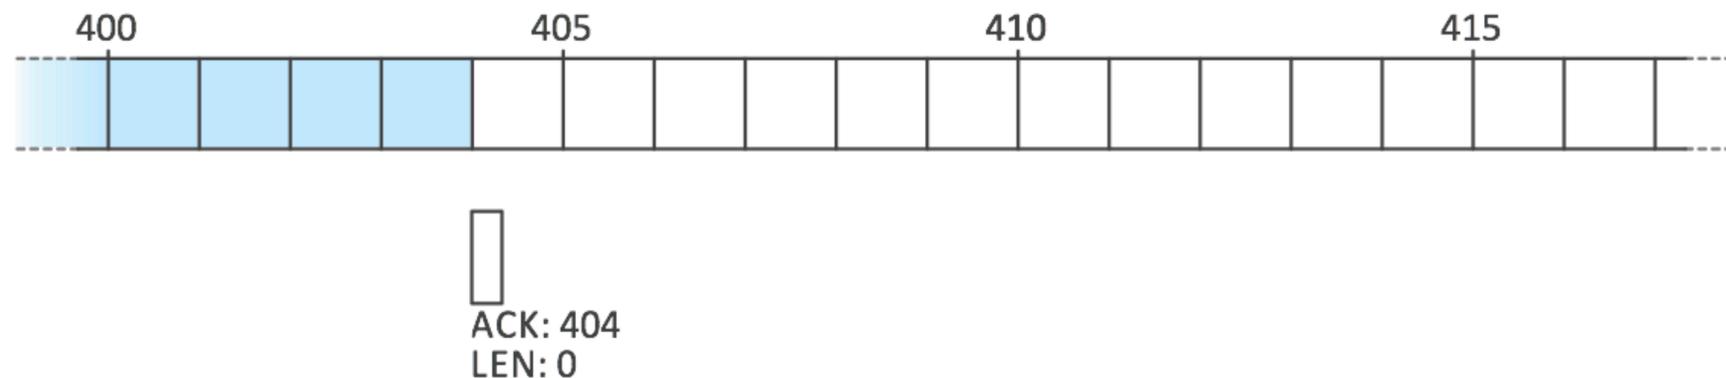

# Transmission Control Protocol

- Sender sends 3 byte segment
- Sequence number indicates where data belongs in byte sequence (at byte 401)
  - *Note: Wireshark shows *relative* sequence numbers*

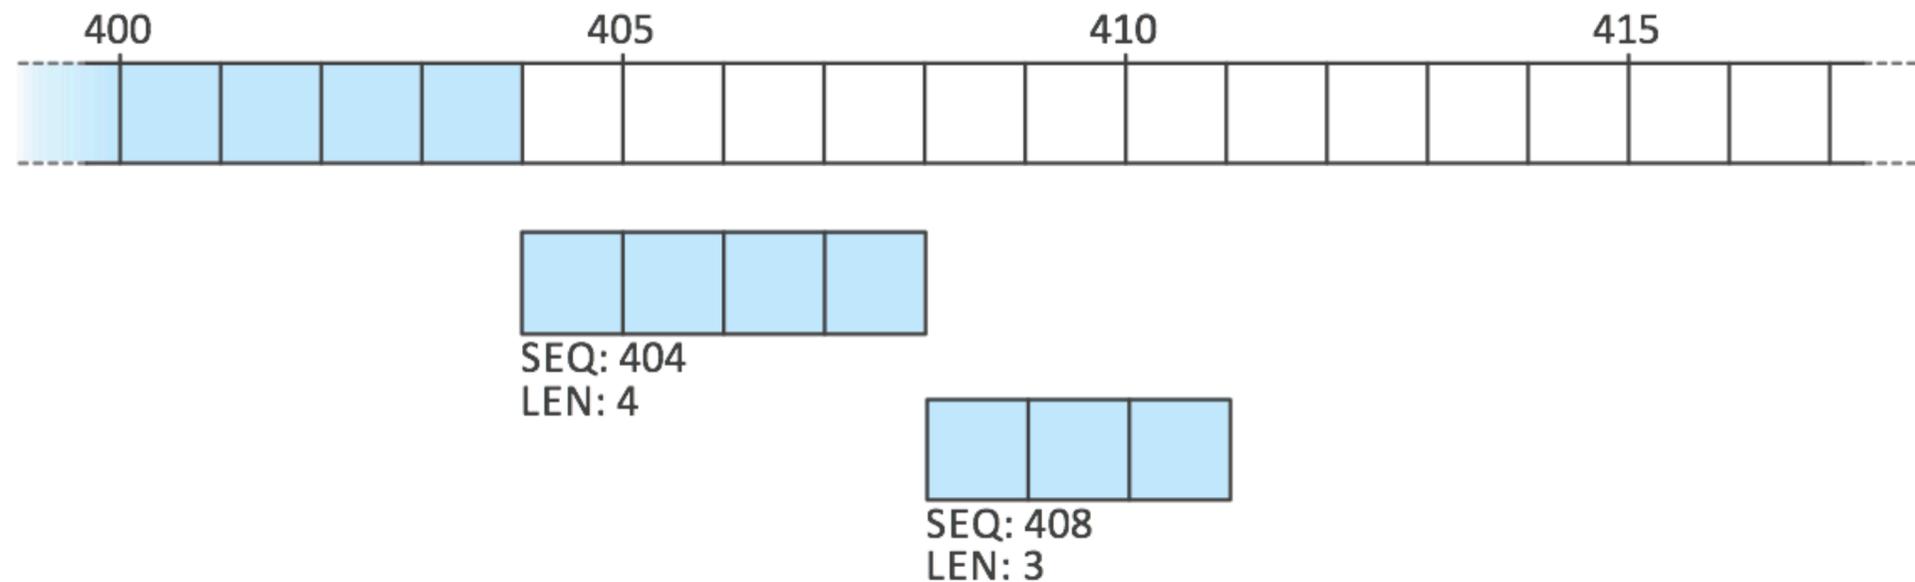

# TCP Acknowledgement Numbers

- Receiver acknowledges received data
  - Sets ACK flag in TCP header
  - Sets acknowledgement number to indicate next expected byte in sequence

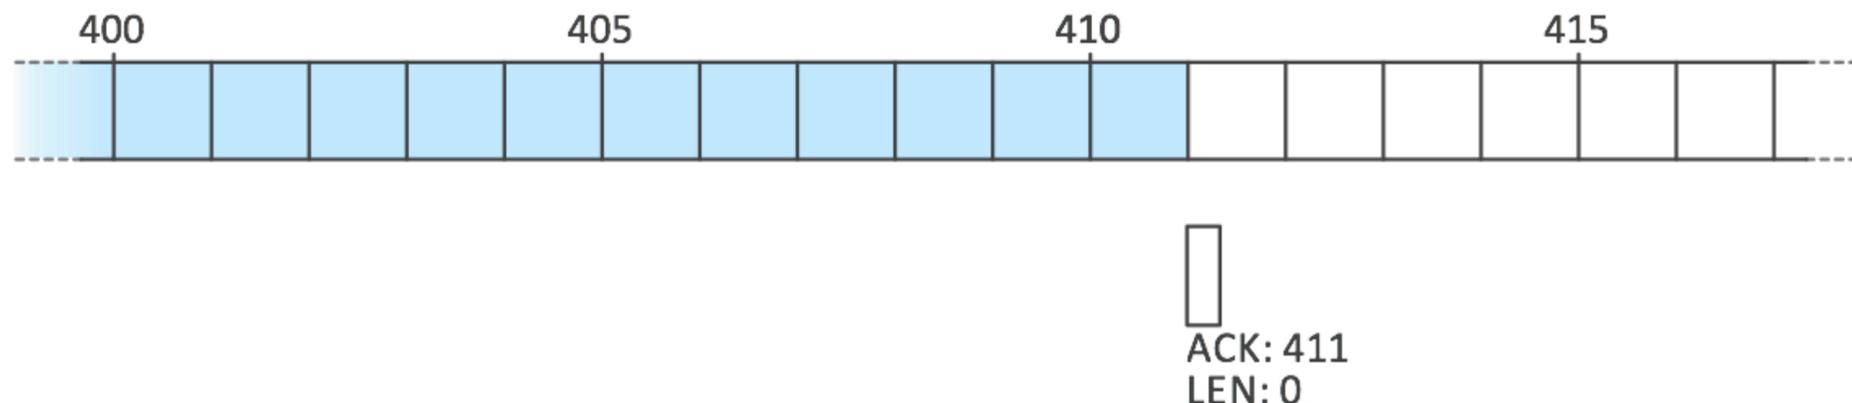

# ACKing Multiple Segments

- Sender may send several segments before receiving acknowledgement

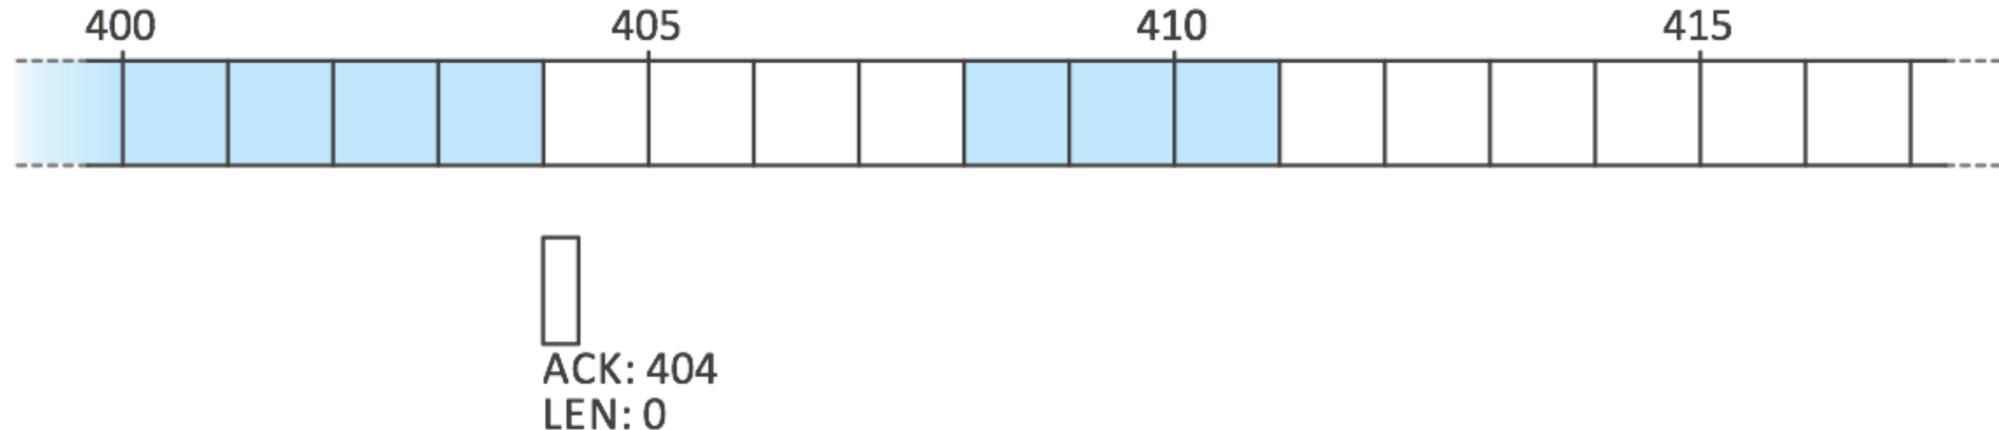

# ACKing Multiple Segments

- Sender may send several segments before receiving acknowledgement
- Receiver always acknowledges with seq. no. of next expected byte

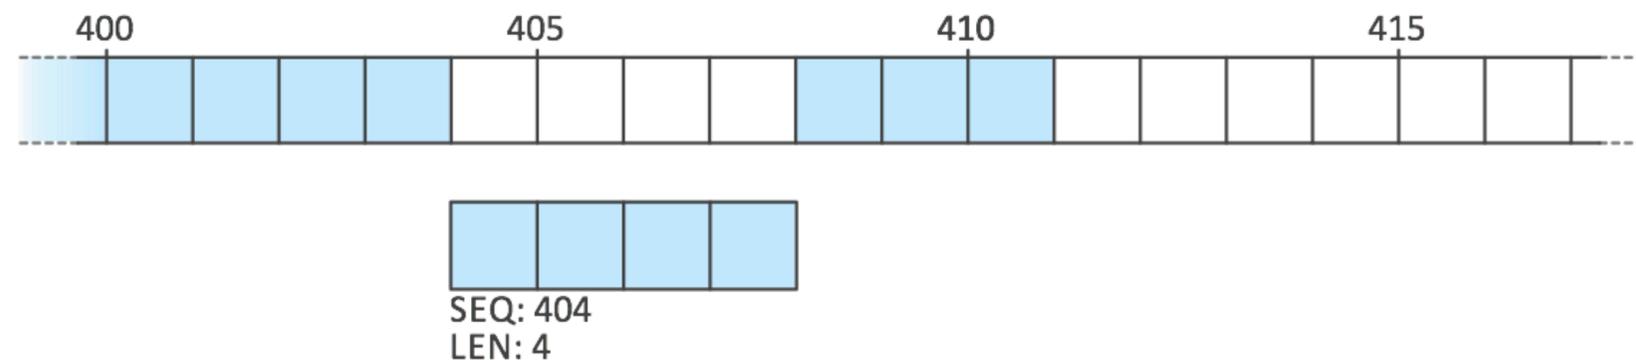

# Transmission Control Protocol

- *What if the first packet is dropped in network?*
- Receiver always acknowledges with seq. no. of next expected byte

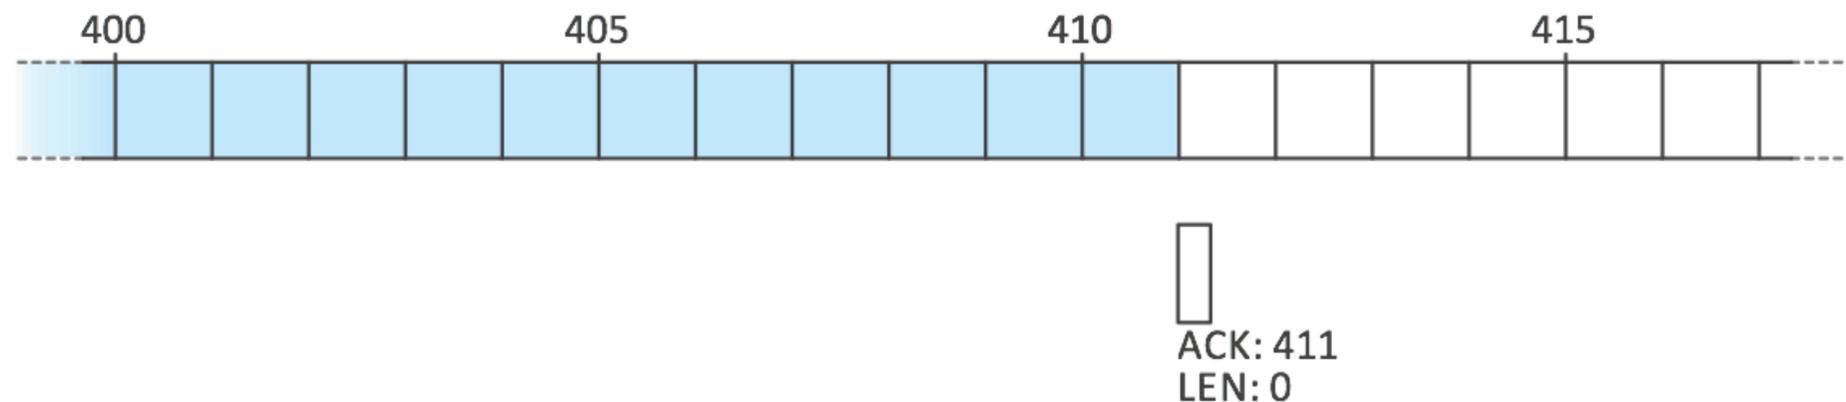

# Transmission Control Protocol

- *What if the first packet is dropped in network?*
- Receiver always acknowledges with seq. no. of next expected byte
- Sender retransmits lost segment

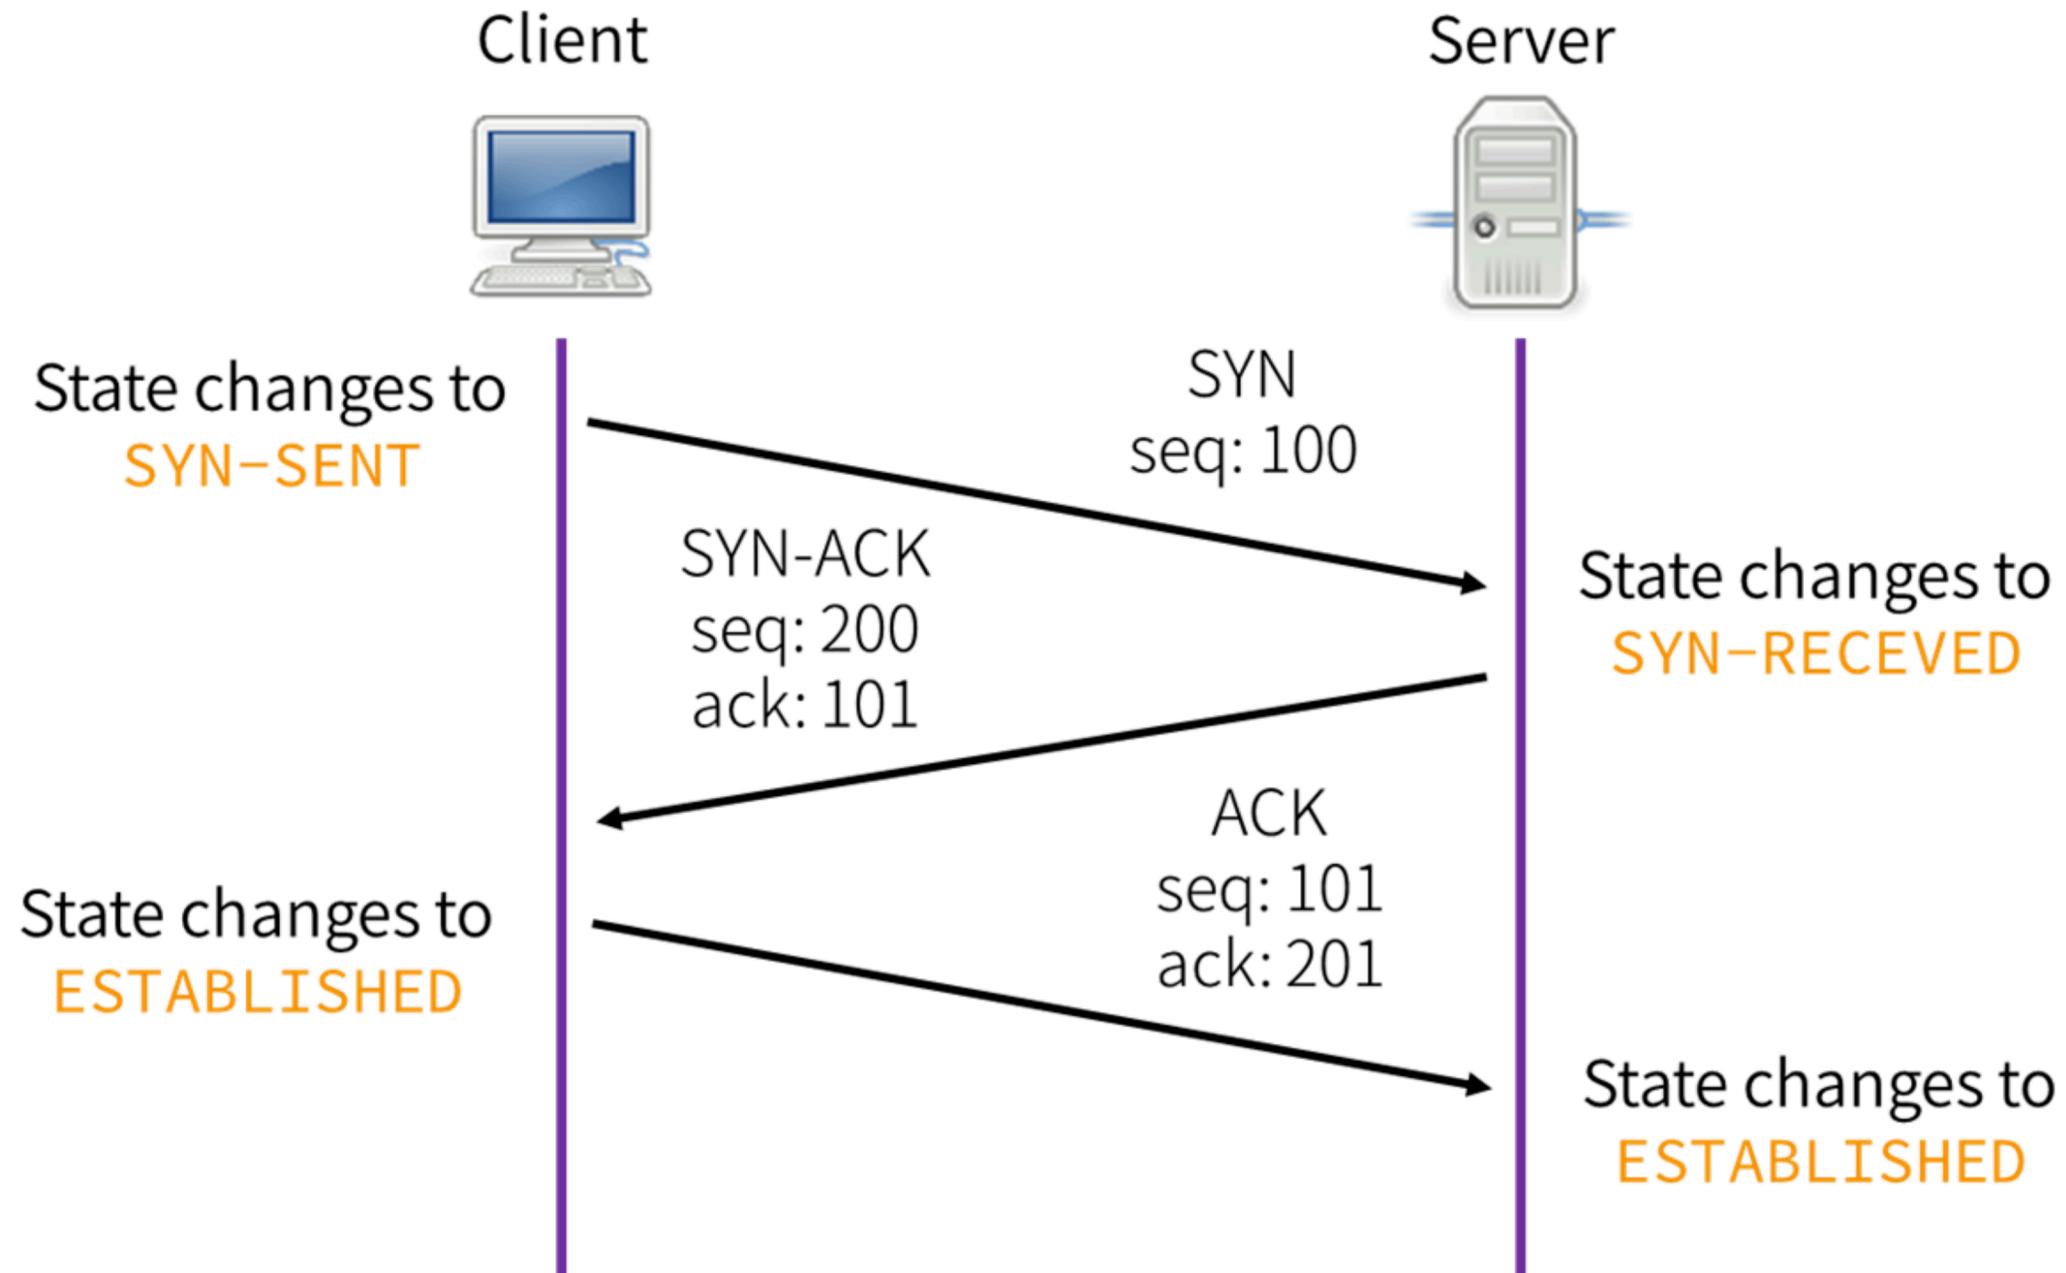

# Transmission Control Protocol

- *What if the first packet is dropped in network?*
- Sender retransmits lost segment
- Receiver always acknowledges with seq. no. of next expected byte

# TCP Three Way Handshake

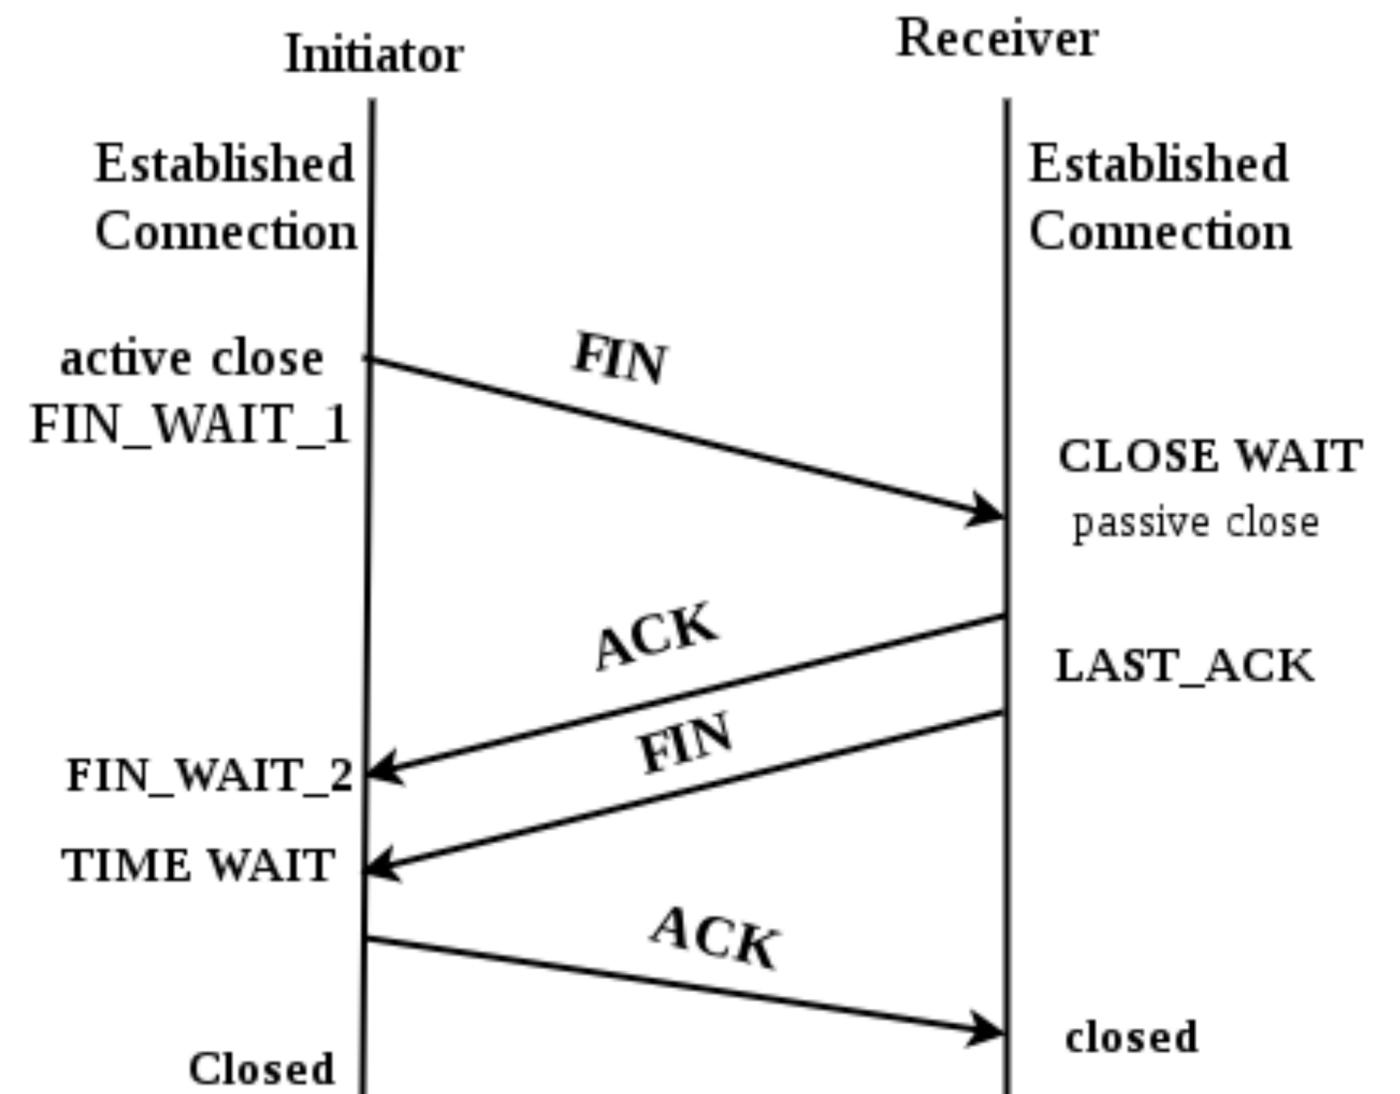

# Ending a Connection

Sends packet with FIN flag set  
Must have ACK flag with valid seqnum

Peer receiving FIN packet acknowledges  
receipt of FIN packet with ACK

FIN “consumes” one byte of seq. number

Eventually other side sends packet with  
FIN flag set — terminates session

# TCP Connection Reset

TCP designed to handle possibility of spurious TCP packets (e.g. from previous connections)

Packets that are invalid given current state of session generate a reset

- If a connection exists, it is torn down

- Packet with RST flag sent in response

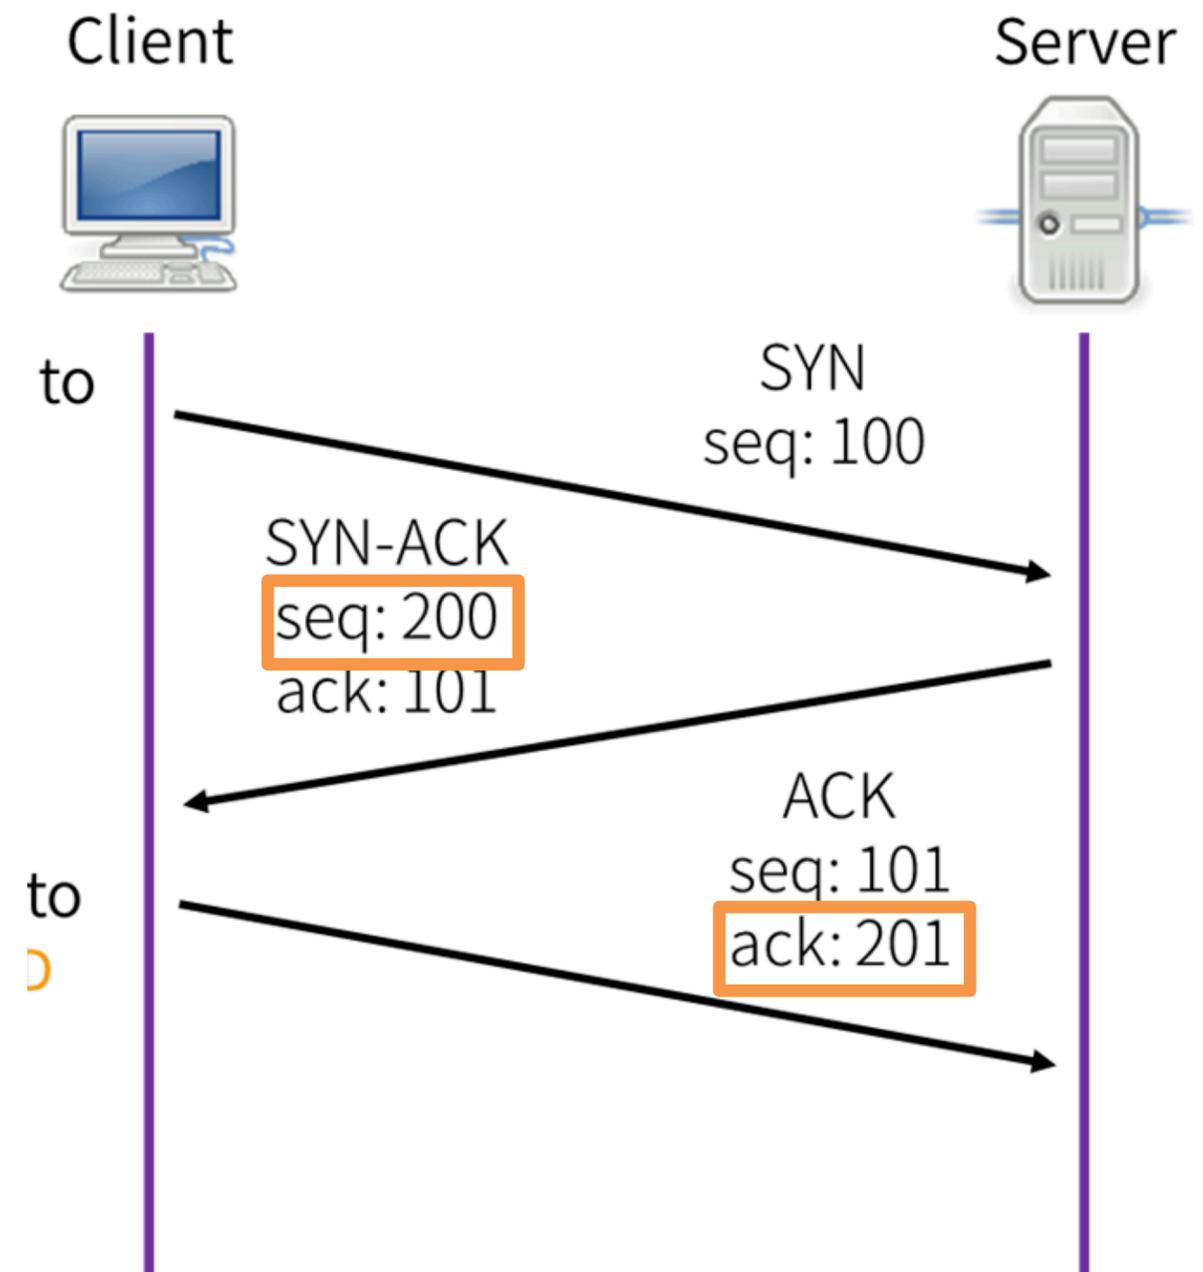

If a host receives a TCP packet with RST flag, it tears down the connection

# TCP Connection Spoofing

Can we impersonate another host when *initiating* a connection?

Off-path attacker can send initial SYN to server ...  
*... but cannot complete three-way handshake without seeing the server's sequence number*

1 in  $2^{32}$  chance to guess right if initial sequence number chosen uniformly at random

# TCP Reset Attack

Can we reset an *existing* TCP connection?

Need to know port numbers (16 bits)

Initiator's port number usually chosen random by OS

Responder's port number may be well-known port of service

There is leeway in sequence numbers B will accept

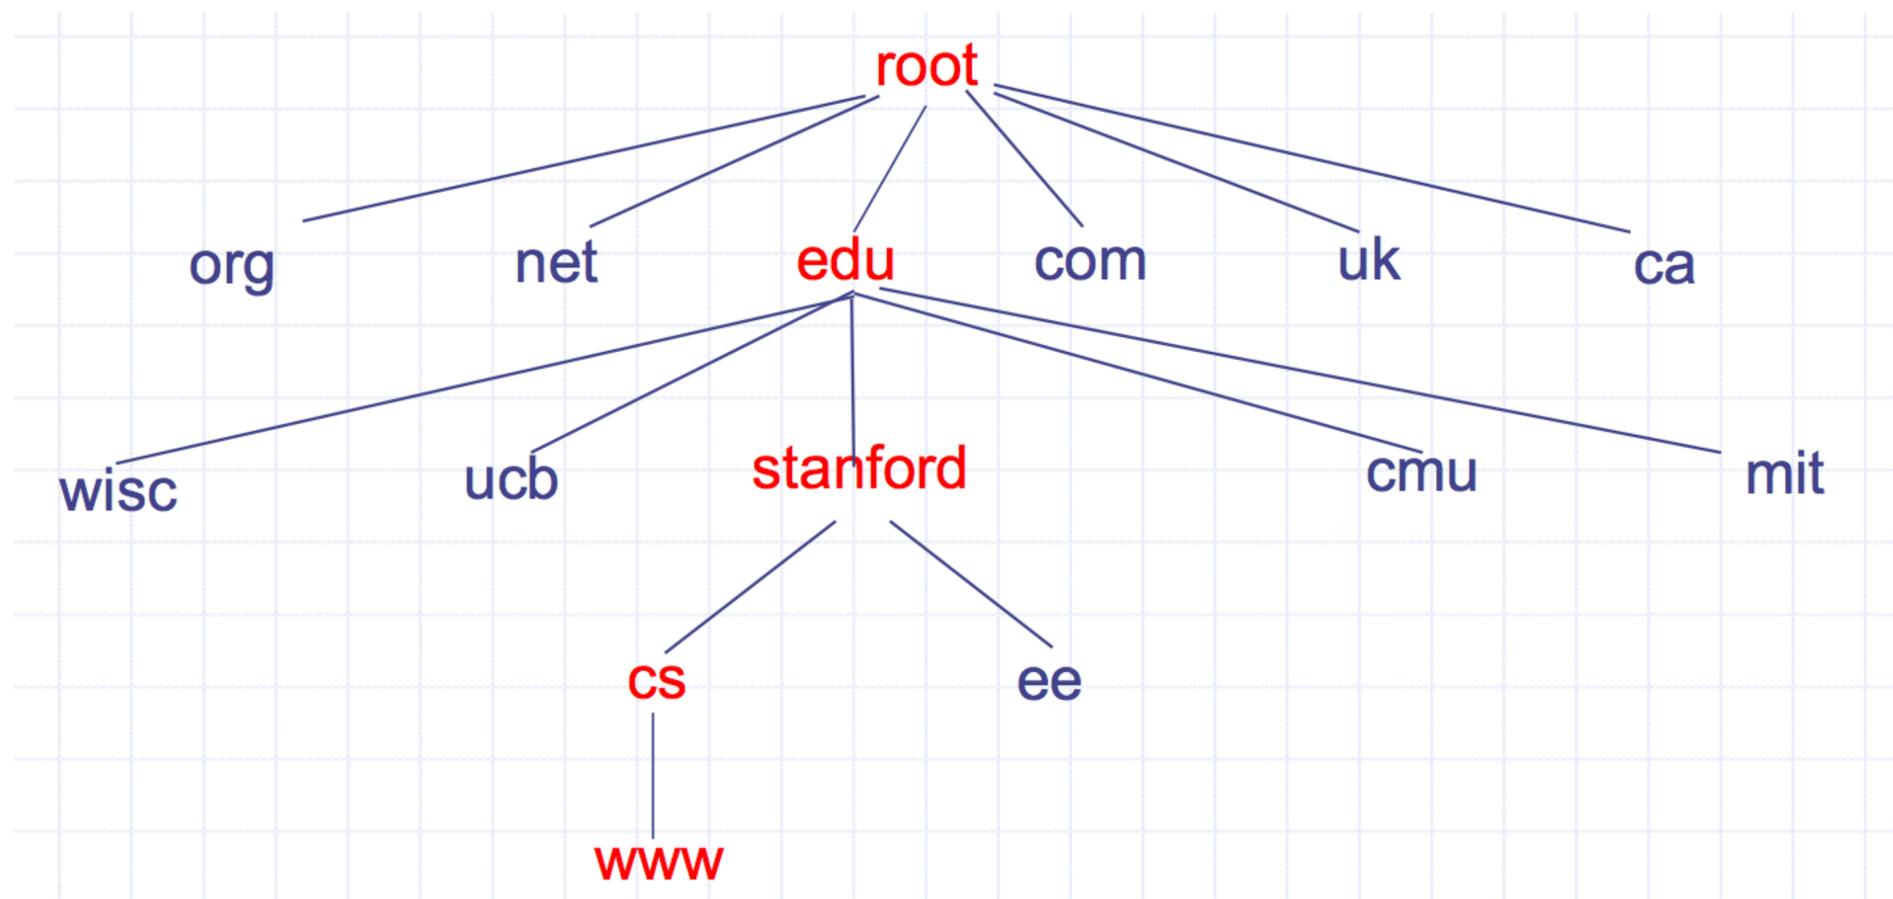

Must be within window size (32-64K on most modern OSes)

1 in  $2^{16+32}/W$  (where  $W$  is window size) chance to guess right

# DNS — Domain Name Service

Application-layer protocols (and people) usually refer to Internet host by host name (e.g., google.com)

DNS is a delegatable, hierarchical name space

# DNS Record

A DNS server has a set of records it authoritatively knows about

# DNS Root Name Servers

In total, there are 13 main **DNS root servers**, each of which is named with the letters 'A' to 'M'.

HOSTNAME	IP ADDRESSES	MANAGER
a.root-servers.net	198.41.0.4, 2001:503:ba3e::2:30	VeriSign, Inc.
b.root-servers.net	199.9.14.201, 2001:500:200::b	University of Southern California (ISI)
c.root-servers.net	192.33.4.12, 2001:500:2::c	Cogent Communications
d.root-servers.net	199.7.91.13, 2001:500:2d::d	University of Maryland
e.root-servers.net	192.203.230.10, 2001:500:a8::e	NASA (Ames Research Center)
f.root-servers.net	192.5.5.241, 2001:500:2f::f	Internet Systems Consortium, Inc.
g.root-servers.net	192.112.36.4, 2001:500:12::d0d	US Department of Defense (NIC)
h.root-servers.net	198.97.190.53, 2001:500:1::53	US Army (Research Lab)
i.root-servers.net	192.36.148.17, 2001:7fe::53	Netnod
j.root-servers.net	192.58.128.30, 2001:503:c27::2:30	VeriSign, Inc.
k.root-servers.net	193.0.14.129, 2001:7fd::1	RIPE NCC
l.root-servers.net	199.7.83.42, 2001:500:9f::42	ICANN
m.root-servers.net	202.12.27.33, 2001:dc3::35	WIDE Project

# Caching

DNS responses are cached

- Quick response for repeated translations

- NS records for domains also cached

DNS negative queries are cached

- Save time for nonexistent sites, e.g. misspelling

Cached data periodically times out

- Lifetime (TTL) of data controlled by owner of data

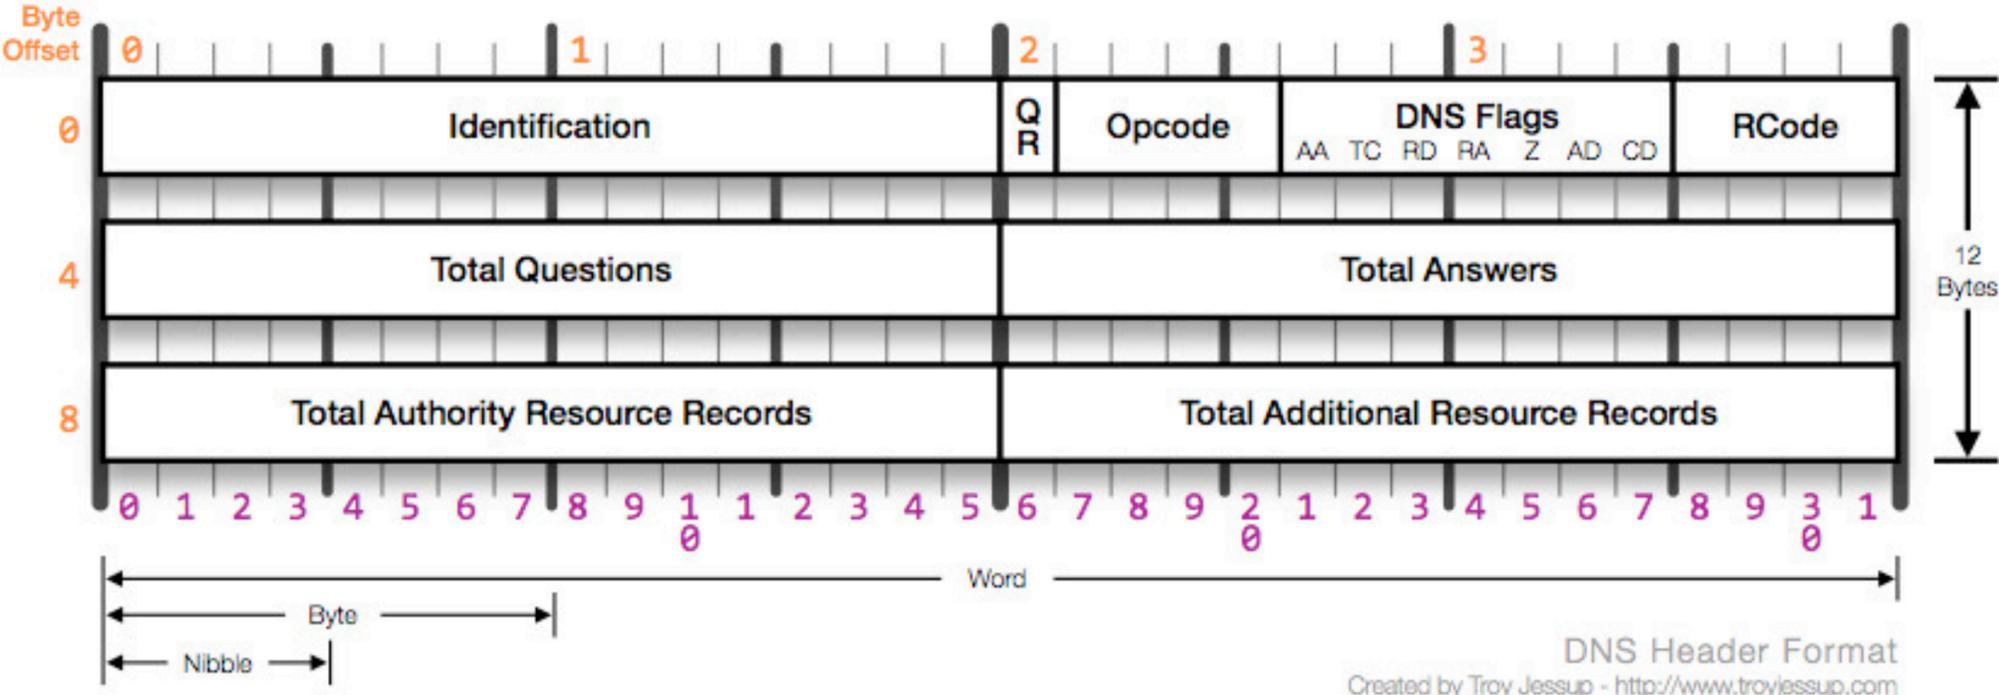

- TTL passed with every record

# DNS Packet

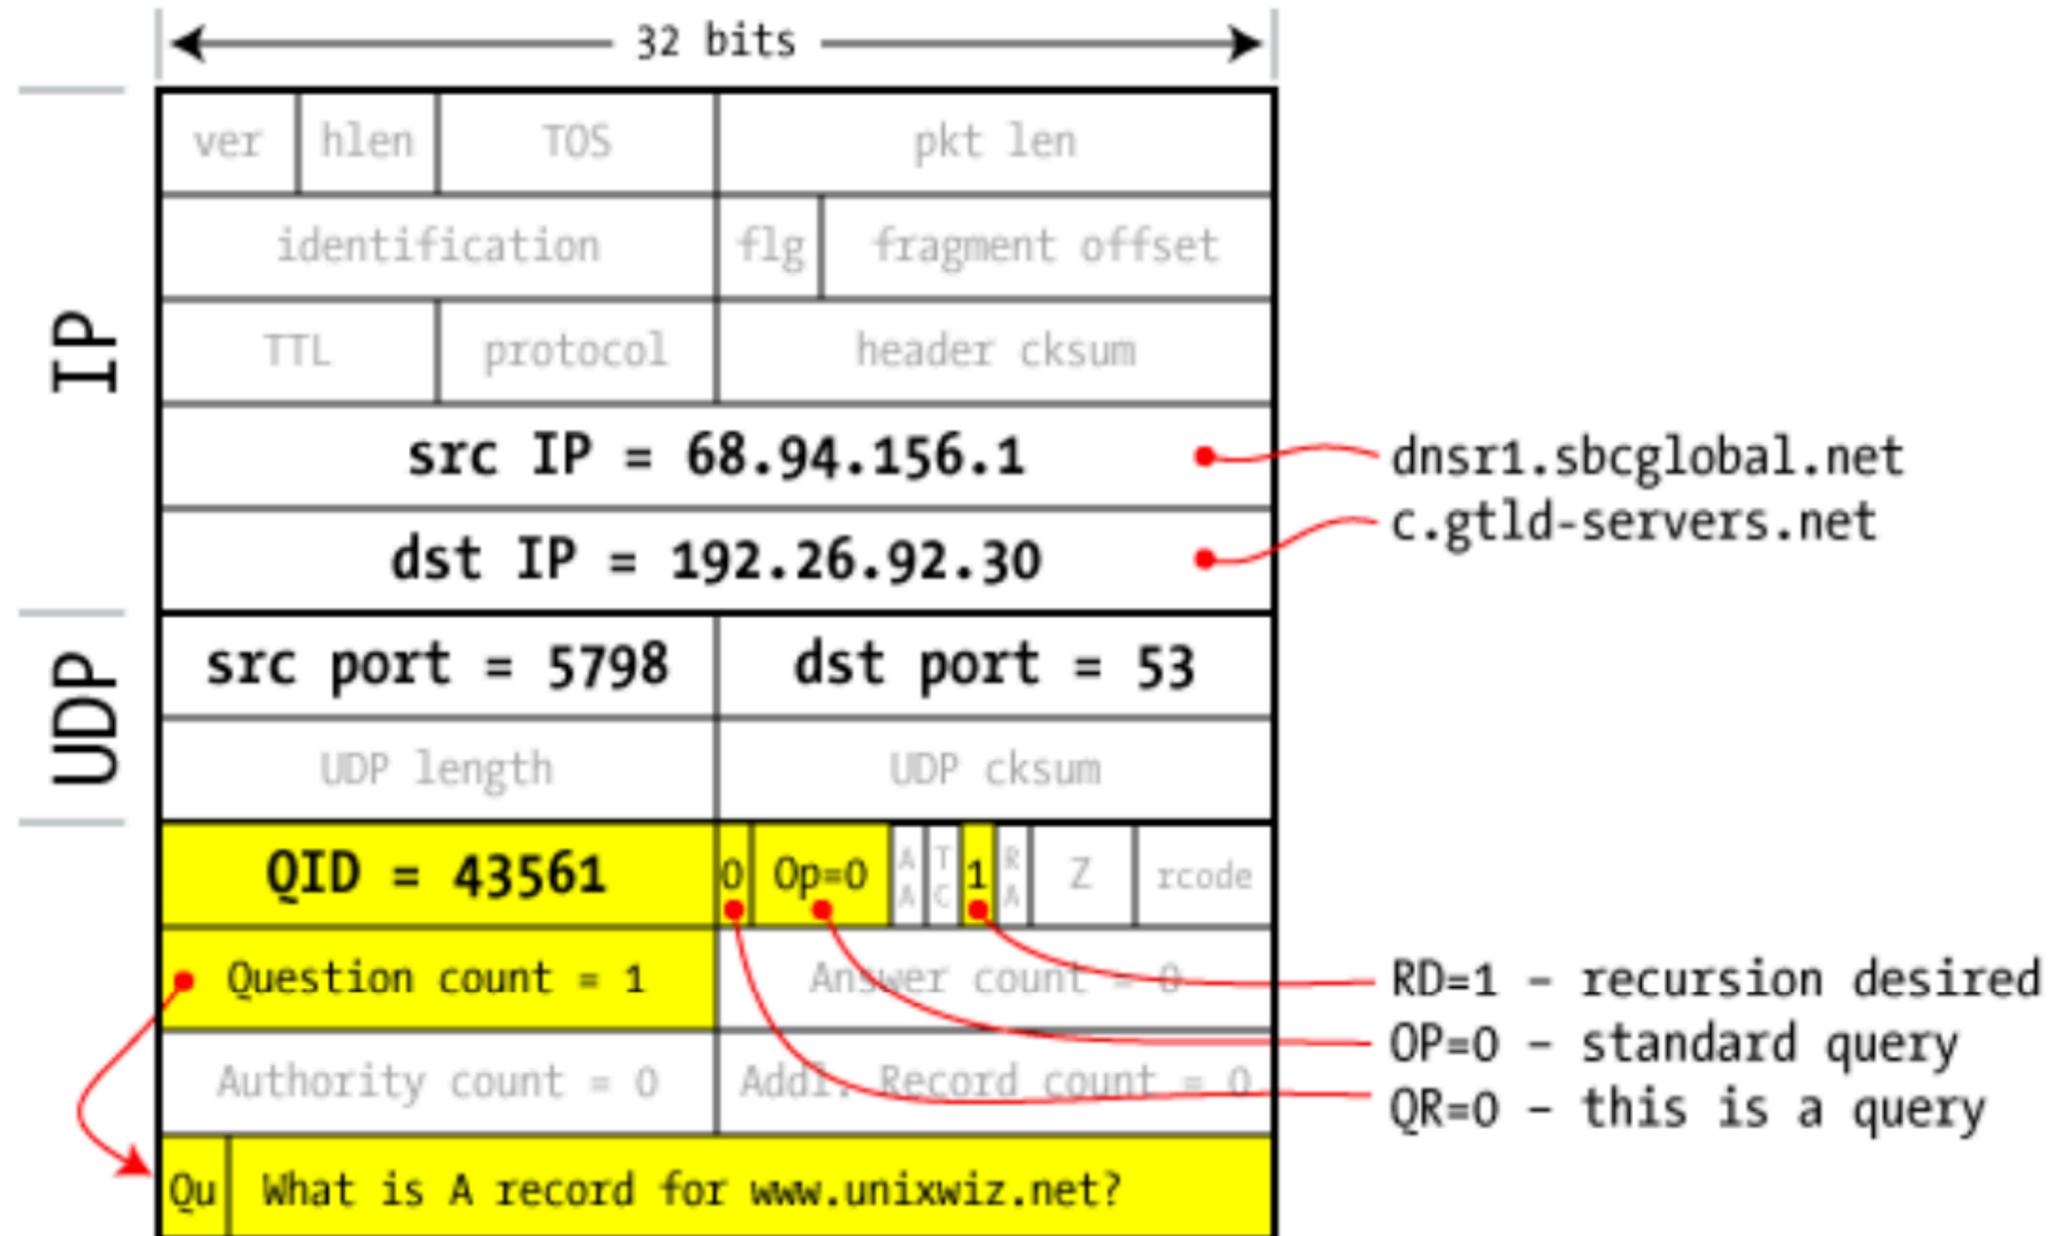

DNS requests sent over UDP

Four sections: questions, answers, authority, additional records

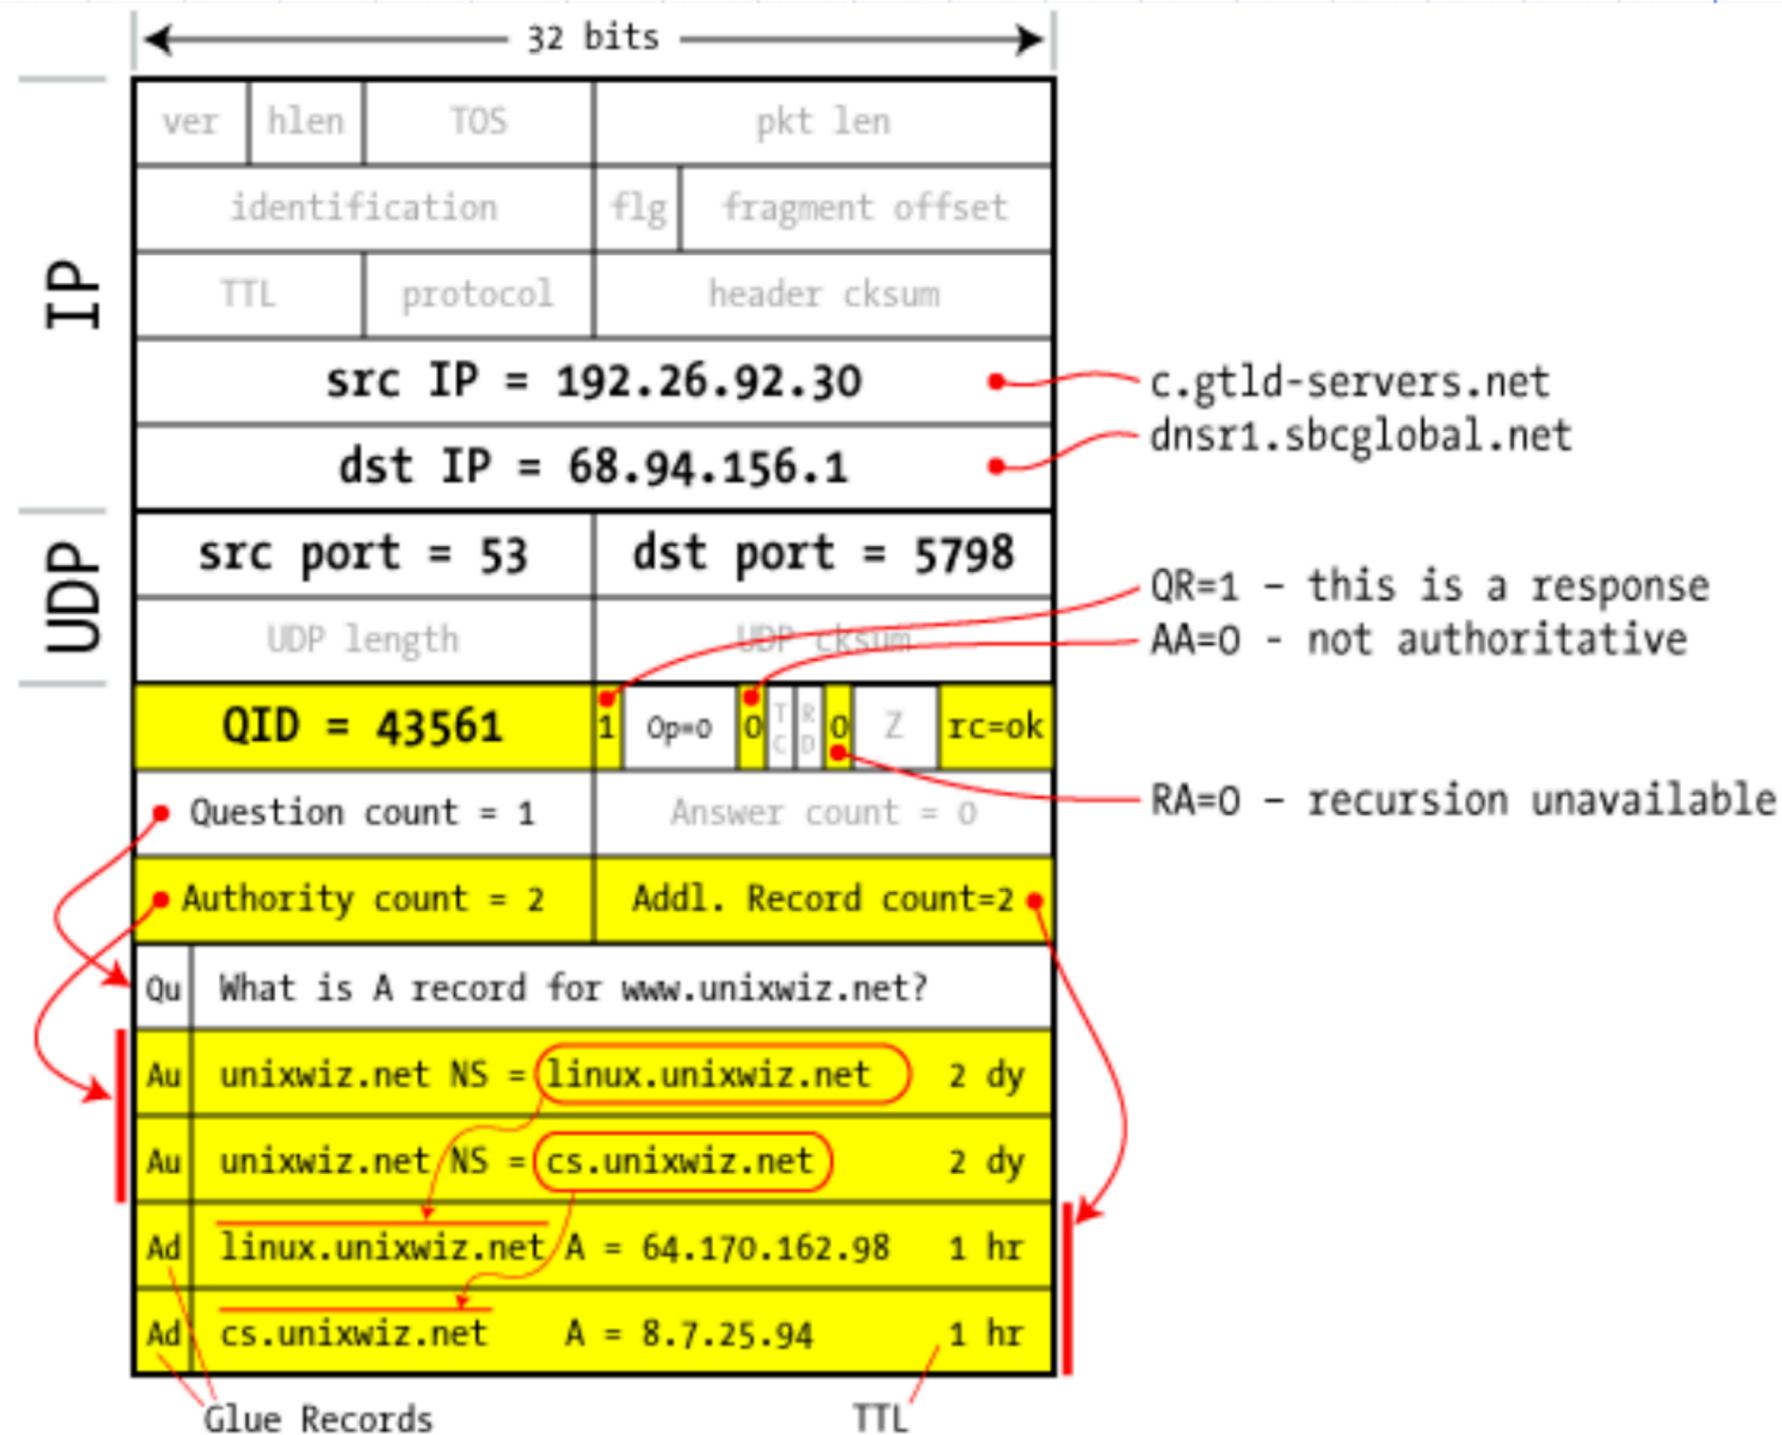

Query ID:  
16 bit random value  
Links response to query

# Request

# Response

# Authoritative Response
